MESSAGE

Groundwater is the most precious fundamental resource used for drinking purpose, agriculture and for industry. The main source of Groundwater is rainfall. This groundwater is directly associated with the hydrological cycle, which is influenced by the atmosphere and climate. The climatic changes have also drastically affected the rainfall pattern. The impacts of climatic changes coupled with growing population, escalating urbanization, and the increasing demand of water for irrigation practices has led to heavy stress on groundwater resources, which can create a biggest hazard for the State's groundwater future availability. Greater part (92%) of the State is covered by basalt rocks that are unfavourable for groundwater storage. With this adverse background, to tackle the situation, periodical estimation of groundwater resources has become one of the most important aspects.

National level committees are constituted for designing the methodology and norms for carrying out the estimation of groundwater resources of the country. After due modifications in the previous methodologies and norms, recently formulated methodology 2015 is used to carry out the Groundwater Resources Estimation of 2023 of Maharashtra. The Groundwater Resources Estimation for Maharashtra State is jointly carried out by GSDA in association with CGWB.

The Groundwater Resources Estimation of 2023 is carried out on India-Groundwater Resources Estimation System (IN-GRES). The reports are available on the website of IN-GRES. All this exercise of Groundwater Resources Estimation is very much helpful for planning, policy making for different projects related to groundwater conservation, groundwater supplies, groundwater management etc.

I appreciate the efforts of all the officers and staff of GSDA and CGWB involved in the process of completing the Groundwater Resources Estimation of 2023 for the State of Maharashtra. I am keenly looking forward that this report will help in planning better groundwater management.

MESSAGE

Groundwater is one of the most important natural resources of the State. It helps for drinking purpose both in rural as well as urban community. It also supports for irrigation & industry. Groundwater sustains the flow of rivers, streams, and helps to maintain wetland ecosystem. It is of vital importance for sustaining life, health, and integrity of ecosystems.

The availability of groundwater is extremely uneven, in space, time and depth. The uneven distribution of groundwater in the State can be mainly attributed to regional variation of rainfall and highly heterogeneous lithology. Around 92% of the State's area is occupied by hard rocks i.e. basalt, and because of variations in their basic characteristics, physiography and variability in the rainfall, there are restrictions for the groundwater availability.

To assess the availability of groundwater and to ensure maximum accuracy in groundwater estimation, the Central Government has appointed committees from time to time, comprising groundwater experts and has laid down guidelines for this purpose. In Maharashtra estimates of groundwater resources are being carried out based on these guidelines. The Groundwater Resource Estimation of Maharashtra for 2017, 2020, 2022 and 2023 is done based on latest norms and guidelines of the GEC-2015 Methodology.

Taking into consideration variation of rainfall in Maharashtra, which is the most dominant factor in the dynamic groundwater estimation, priority is to be given for demand management measures supported by artificial groundwater recharge in all the over developed (over-exploited/critical/semi-critical) watersheds. Similarly, the convergence of the GoI and GoM schemes of watershed development or artificial groundwater recharge need to be promoted in these areas.

I appreciate the efforts taken by officers of GSDA and CGWB who have been involved in the process of completing Groundwater Resources Estimation of 2023 for the state of Maharashtra. I am optimistic that this report will be useful to the planners, policy makers, farmers, and other stakeholders for better management of groundwater resources in the state.

(Pavneet Kaur, IAS)
Commissioner

Groundwater Surveys and Development Agency,
Government of Maharashtra,
Pune

PREFACE

Central Ground Water Board, Ministry of Jal Shakti, Govt of India in coordination with Groundwater Surveys and Development Agency, Government of Maharashtra has taken up the reassessment of **“Dynamic Groundwater Resources of Maharashtra-2023”** based on the latest techniques and data. The National Water Policy of India, regards groundwater as one of the most crucial elements in development planning. Therefore, accurate assessment of this vital resources is to be done at periodic interval by using the latest data & technology. The earlier estimates were carried out for the year 2004, 2009, 2011, 2013, 2017, 2020 and 2022.

Presently groundwater contributes 80 % of domestic needs and ~50% of irrigation needs of the people from the state. Demand on groundwater resources is further increasing due to pace of industrial development which, often leading to unsustainable drawl of groundwater resources from deeper aquifers.

The state which receives a normal annual rainfall between 882 mm to 3000 mm is mainly underlain by basalt (hard rock) aquifers (82% of geographical area), other aquifers are namely, gneisses, Schists & granite, (11%), rocks belonging to Precambrian age (2%) and alluvium (5%). The Water level data is monitored 4 times a year by CGWB from its 2124 monitoring wells and GSDA also monitors water level from its existing 3700 wells and this data is used extensively in computation of resources.

As compared to 2022 assessment, the Annual Ground Water Recharge in 2023 has increased from 32.28 to 32.76 BCM, Annual Extractable Ground Water Recharge from 30.45 to 30.95 BCM and Annual Ground Water Extraction from 16.65 to 16.66 BCM. There is a marginal decrease in the Stage of Ground Water Extraction by 0.85% i.e., from 54.68 % to 53.83 %.

I appreciate the efforts made by GSDA officials led by the Commissioner and his team of officers from Hqrs and officials from districts. I also put on record the sincere efforts made by officers from CGWB namely Dr. Pandith Madhnure, SC-D, Dr. Davithuraj, Sc-D, Sh. Modi Durgaprasad, Sc-C, Dr. P. Kiran Kumar, Sc-C and Smt. Bhagyashree Sahoo, SC-B. I also thank the committee members of SLC under the chairmanship of Adl. Chief Secretary, WS & SD, Govt of Maharashtra for giving their valuable comments in finalizing the report. The constant guidance and support provided by Chairman, CGWB, is duly acknowledged.

I, sincerely hope that the present report will serve as useful tool to the administrators, planners and government authorities in decision making and planning of groundwater schemes and regulation at field level.

Nagpur

Date: 27/03/2024

CHAPTER- 1

1. INTRODUCTION

The estimation of ground water resources of Maharashtra state as on 2023 has been carried out as per the recommendations of Ground Water Estimation Methodology-2015 (GEC-15). Earlier methodology (GEC- 97) is based on ‘**Water Balance Approach**’ and the GEC 97 norms were used for estimation of dynamic ground water resources of the country considering 2004, 2009, 2011 and 2013 as base years. The methodology underwent comprehensive revisions in 2015 and a revised methodology, namely GEC 2015 methodology has been prescribed for ground water assessment. This methodology is followed for the assessment carried out since 2017 onwards. The revised methodology GEC 2015 recommends aquifer wise ground water resource assessment. Wherever the aquifer geometry has not been firmly established for unconfined aquifer, the in-storage ground water resources have to be assessed in alluvial areas up to depth of bed rock or 300 m whichever is less. In case of hard rock aquifers, the depth of assessment would be limited to 100 m. In case of confined aquifers, if it is known that ground water extraction is being taken place from this aquifer, the dynamic as well in-storage resources are to be estimated. If it is firmly established that there is no ground water extraction from this confined aquifer, then only in-storage resources of that aquifer have to be estimated.

Groundwater resource assessment is the determination of the source, extent, dependability and quality of groundwater, on which the evaluation of the possibilities of the utilisation and control depends. Estimation of groundwater is also important for managing State’s water supply infrastructure, especially those that are dependent on groundwater. This report provides an overview of the groundwater resources of Maharashtra for use in like agricultural, domestic and industrial water supply. It will form the basis for understanding the existing and planning the future use of groundwater and to decide the management options on a holistic basis. These data also provide inputs that would be used to understand the dynamics of various sector wise demands and ensure sustainability for different water sector activities. The near approach accuracy in groundwater resource assessment will help the planners and policy makers in determining the extent and nature of:

- Co-ordinating and integrating mechanisms, now, required in the field of water sector.
- Regulations and new legislation, and Strategies and policies that deal with the priority of uses and conflict resolution mechanism (through mutually beneficial bargaining- basin/sub-basin water partnerships).

In short, groundwater resources assessment is a prerequisite for sustainable development of States water resources.

The present availability and requirement of water in the State of Maharashtra is extremely uneven, both spatially and temporally and so will be case in the future. Rapid population growth and

intensive anthropogenic activities have put both surface and groundwater under heavy stress, and significantly fresh water is becoming scarce and dearer in many areas. It is believed that in the coming decades most of the Earth's population will face a critical situation with regard to the availability of water. The water deficiency will become a factor affecting the living standards of populations adversely. To understand more about the water resource deficit that will face us in the future it is very important to analyse the present situation and understand rate of change in specific water resource availability in relation to socio-economic, geohydrologic and physiographic conditions.

In the State of Maharashtra, groundwater is an essential component for many water strategies and systems. It is therefore essential that the groundwater resource estimation is accurate so as to prepare strategies for the long-term management of this precious resource and for ensuring the long-term safety and wellbeing of all the sections of the society.

Groundwater resource estimation is mainly dependent on the quality of the data. Many a times because of the lack of good quality data the resource assessment misleads the planners, administrators and technocrats in formulating various developmental activities. Even today, the situation is no better. Systematic information on groundwater withdrawal by various sectors, especially irrigation and industry, through different groundwater structures is unavailable. Even with sincere efforts made by the Groundwater Surveys and Development Agency and CGWB it was not possible to obtain the required data, like estimated abstraction of groundwater from the wells from the well census data.

The State of Maharashtra is covered mostly by highly heterogeneous and structurally complicated rock formations, wherein it is very difficult to generalise any methodology or guidelines on hydrogeological aspects. In Deccan Trap Basalt, there is no well-defined, uniformly distributed, homogeneous aquifer system. Even during the process of recharge, the surface water in the given area does not uniformly replenish the subsurface. For assessing the groundwater resources on a regular basis, it is necessary to determine certain hydrogeological factors, which define the groundwater regime. This includes precipitation, storativity of the bedrock, aquifer characteristics, water quality and the overall environment.

Maharashtra is one of the few States in the country to initiate the work of aquifer delineation and subsequent management of groundwater resources. The implemented pilots illustrated the path breaking results.

1.1 BACKGROUND

In the State of Maharashtra groundwater has emerged as an important source to meet the water requirements of various sectors. Demands for groundwater resources are ever increasing and competition amongst users has intensified. The sustainable development of groundwater requires precise quantitative assessment based on reasonably valid scientific principles. The occurrence, movement and storage of groundwater are quite complex, being governed by several factors like

meteorology, geomorphology, geology, hydrogeology, and above all the human activities. All these factors make the precise assessment of groundwater very difficult and there is no direct technique available for precise assessment. Hence the methods applied for groundwater resource estimation are all indirect. There are several techniques and methodologies *in vogue* for estimation of groundwater resources. Quantification of groundwater resources is often critical and no single comprehensive technique is yet identified which is capable of estimating accurate groundwater potential. Since groundwater is a dynamic and replenishable resource, its proper and economic development on a sustainable basis, requires its realistic assessment. The estimation must be seen as an interactive procedure. Initial estimation are revised and refined by comparing these results with the results obtained by adopting alternative methods and third party studies.

The Ministry of Jal Shakti, Dept. of Water Resources, River Development & Ganga Rejuvenation, Govt. of India desires to reassess the Ground Water Resources for the entire country annual basis and hence the current re-estimation of resources as in March 2023 has been taken up in view of the changes that are observed in the ground water scenario. The last year data provided by the state agencies have been used in present ground water assessment. During current assessment, a software named “INDIA-Groundwater Resource Estimation System (IN-GRES)” has been introduced for re-assessing the ground water resources of entire country. The data collected were compiled as per format and was uploaded in the software and the results generated were validated with the manual calculations for ensuring the error-free functioning of software. The results were cross checked at various hierarchical levels.

1.2 CONSTITUTION OF COMMITTEE FOR MAHARASHTRA

The assessment of ground water resources for the State of Maharashtra have been estimated by the Ground Water Survey and Development Agency (GSDA) in collaboration with the Central Ground Water Board (CGWB), Nagpur based on the revised GEC-2015 Methodology. The present exercise on groundwater assessment as on March 2023 is also carried out in accordance with the protocol of GEC-2015 under the supervision of State Level Committee (SLC) of the respective States/UTs and under overall guidance of Central Level Expert Group (CLEG).

The SLC committee was constituted vide GR. No. Bhujal-1822/C.R. 29/WS-15 dated 27.01.2022. the copy of Govt resolution is enclosed as Enclosure -I. the RD CR is the member secretary of the committee.

State Govt. vide letter no. Bhujal-1822/C.R.29/WS-15 constituted The Permanent State Level Committee for Estimation of Ground Water Resources based on GEC-2015 Methodology (Enclosure-II).

As suggested in the protocol, the Groundwater Assessment Cell has been formed at State Level within the Directorate of Groundwater Surveys and Development Agency, Pune. The identification of data gaps and updating of database with respect to 2023 has been done in the cell. The entire data base has been reconciled jointly by GSDA and CGWB, Nagpur in a series of online/physical meetings, email correspondence and verification.

1.3 BRIEF OUTLINE OF THE PROCEEDINGS OF THE COMMITTEE

The State Level Technical Committee was held under the Chairmanship of Shri Sanjay Khandare, IAS, Principal Secretary, Department of Water Supply and Sanitation, Govt. of Maharashtra, Mumbai on 04th September 2023. The meeting was held in hybrid mode for finalization of Ground Water Resource Estimation 2023 (GWRE-2023) for the State of Maharashtra jointly carried out by Ground Water Surveys & Development Agency (GSDA), Pune and Central Ground Water Board (CGWB), Nagpur. Sh. N. Varadaraj, Regional Director & Member Secretary convened the meeting and the concerned Members of SLC participated during the meeting.

During the meeting, Dr. Vijay Pakhmode, Joint Director, GSDA, Pune made a detailed presentation on ground water resource assessment of Maharashtra component-wise (recharge & discharge) as on 2023 and also compared it with the previous assessment 2022.

During the discussions, the Chairman of the committee and Principal Secretary appreciated the efforts of CGWB & GSDA in completing the assessment and finally approved the Dynamic Ground Water Resources - 2023 (GWRE-2023) for the state of Maharashtra.

CHAPTER- 2

2.1 LOCATION & AREAL EXTENT

Maharashtra, the third largest state in India has a total geographical area of 3,07,713 sq km and lies between latitudes of 15°40' and 22° 00' N and longitudes of 72° 30' and 80° 30' E in the west-central part of India abutting on the Arabian Sea. The State is governed by administrative by 36 districts

and including 2 urban districts and 357 talukas. There are 336 cities and towns in the State, out of which 40 have population more than 100,000. There are 40,785 villages and 45,528 hamlets (*wadi*, *vasti* or *pada*). District administrative boundaries considered for Groundwater Resource Assessment is shown in **Map 1**. The Salient features of State are given in Table-1

Table-1: SALIENT FEATURES OF MAHARASHTRA

A	Location	
	Latitude	15°40' to 22°00' E
	Longitude	72°30' to 80°30' N
	Area	3,07,713 sq. km
B	Physiography	1. The Sahyadri Range (Western Ghats) 2. The Western Coastal Tract (Konkan) 3. The Eastern Plateau (Deccan Plateau)
C	Population (census 2011)	112,374,333 (112.37 million) (Male-58.3 million and Female-54.0 million)
	Urban Population	50.81 million (45.23%)
	Rural Population	61.56 million (54.77%)
C	Rainfall Zone	
	High Rainfall	2000 to 3500 mm
	DPAP Area	400 to 700 mm
	Assured Rainfall	800 to 1250 mm
D	Land Use (2019-2020)	
	Area under Forest	61936 sq. km
	Gross Cropped area	232.12 sq.km. as per SER
	Net area Sown	168.15 sq.km
	Soils	Lateritic Soil, Shallow Black cotton soil, Deep Black cotton soil
	Plains and Central Highlands	Brown to black calcareous loams and clay
E	Western Ghats and Peninsular Plateau	Shallow brown to dark brown gravel, loams on high slopes, red to reddish brown laterites and lateritic soils on high level
	Coastal Plains	Laterites and lateritic soils red to reddish brown loam of non-lateritic origin
	Geology	
	Quaternary Alluvium	14498 sq. km (5.71%)
F	Deccan Trap lava flows	250026 sq. km (81.25%)
	Gondwana Rock Formation	4808 sq. km (1.56%)
	Proterozoic's	6190 sq. km (2.01%)

	Precambrian Basement Complex	32191 sq. km (10.46%)
	<i>Cropping Pattern</i>	
	Konkan	Paddy, horticulture and vegetables
G	Western Maharashtra	Jowar, wheat, sugarcane, groundnut, onion, horticulture, sunflower, etc.
	Central Maharashtra	Jowar, wheat, cotton, sugarcane, grams, vegetables, sunflower, safola
	Vidarbha	Paddy, Jowar, Wheat, Cotton, Orange, Grams, Chilli
	Khandesh	Jowar, maize, grams, banana, wheat and chilli
	<i>River Basins</i>	5 basin & 15 sub basins
	<i>Godavari</i>	1,52,811 (49.8%)
H	<i>Krishna</i>	69,032 (22.6%)
	<i>Tapi</i>	51,304 (16.8%)
	<i>Coastal (westerly flowing)</i>	33,228 (10.80%)
	<i>Narmada</i>	1,417 (0.006%)
	<i>watersheds</i>	1535

2.2. PHYSIOGRAPHY & DRAINAGE

Physiographically, the State can be divided into three units: a) The Sahyadri Range (Western Ghats) b) The Western Coastal Tract (Konkan) and c) The Eastern Plateau (Deccan Plateau). The state is divided into 6 major basins namely Godavari, Krishna, Tapi, Narmada, Mahanadi and Coastal (westerly flowing) (Map 2). About 75% area of Maharashtra is drained by the eastward flowing rivers, viz., the Godavari and the Krishna before they join to Bay of Bengal sea and the remaining 25% area is drained by westward flowing rivers, viz., the Tapi and the Konkan coastal rivers, to the Arabian Sea.

2.3. POPULATION

As per 2011 census, the population of state is 112.37 million out of which 45.23 (40.25%) million is urban and 54.77 (48.75%) million is rural. The state is mainly an agriculture State with around 82% of rural population relying on agriculture.

2.4 AGRICULTURE

Agriculture is the mainstay of the state of Maharashtra. Maharashtra's economy is predominantly agrarian. Both food crops and cash crops are grown in the state. Principal crops include rice, jowar, bajra, wheat, pulses, turmeric, onions, cotton, sugarcane and several oil seeds including groundnut, sunflower and soybean. The state has huge areas, under fruit cultivation of which mangoes, bananas, grapes, and oranges are the main ones. The agriculture in state is predominantly rain-fed.

2.5 CLIMATE & RAINFALL

The climate of Maharashtra State is tropical monsoon type. Its location on the Western Coast and the peculiar topography are additional features which cause regional variation of climate from place to place within the State.

Maharashtra predominantly receives 85% of rainfall from the SW monsoon (from June to September). The monsoon normally withdraws by the end of September or early October. The distribution of rainfall across the State is variable and is strongly influenced by physiography. The

Western Ghats, popularly known as the ‘*Sahyadri*’ rises up from the coastal plains- ‘Konkan’ upto a maximum height of 1654 m. It forms a fairly continuous hill range in the north-south direction and forms a major water divide along the western parts of the State. The Konkan coast experiences high rainfall up to 3000 mm. The *Sahyadris* also act as a barrier to the advancing southwest monsoon and also receive copious rainfall. However, they form a rain shadow zone on the eastern side where the rainfall is generally between 400-700 mm but at times less than 400 mm. This region constitutes the Drought Prone Area of the State. Thus, the central part of the State almost always reels under scarcity and droughts. Ninety-nine talukas in the State are chronically drought affected. The region towards east of Marathwada and Vidarbha receives up to 1250 mm rainfall and falls within the assured rainfall zone. Variability of rainfall over the State is generally high ranging from 20 to 35 %, except in coastal areas where it is less than 20% (Map 3)

The post-monsoon season generally extends for two months between October and November. The winter season lasts for three months from December to February. March, April and May form the hot weather season.

2.6. EVAPORATION

The evaporation in state varies from 1478 mm to 2474 mm. It is lowest in Konkan region where as highest in Nashik, Dhule, Jalgaon, Buldhana, Akola and Amravati districts. If mean monthly evaporation and mean monthly rainfall are compared the evaporation appears higher even than rainfall in the months of July and August in Ahmednagar District and in September in Jalgaon, Buldhana and Akola Districts. That is why, even during monsoon, crops are badly in need of irrigation in these districts.

2.7 GEOLOGY

The geology of Maharashtra is famous for the Deccan Traps, which occur in all the districts of the State, except Bhandara, Gondia and Gadchiroli. The other geological formations, older and younger than Deccan Traps, occur in the northeast and as isolated patches in the Sindhudurg and Ratnagiri districts (Map 4). The stratigraphic succession of the geologic formations in the State is given in Table -2.

TABLE 2- Stratigraphy of rock types occurring in Maharashtra

Age	Geology	Distribution in the districts Covered
Recent-Quaternary	Alluvium	Alluvium in parts of Dhule, Nandurbar, Jalgaon, Buldhana, Akola and Amravati districts.
	Laterite	Laterites in Kolhapur, Satara, Sangli, Ratnagiri, Raigad and Thane districts.
	Beach Deposits	Beach sand along the beaches, Konkan coast
Lower Eocene Upper Cretaceous	Deccan Trap Volcanic Lava flows with inter-trappean beds.	All the districts of the State except Bhandara, Gondia, Gadchiroli
	Lametas	Nagpur
	Bagh Beds	Nandurbar
Jurassic (Up. Gondwana)	Chikiala and Kota Stages: Limestone.	Sironcha taluka of Gadchiroli district.
Triassic	Pachmari and Maleri Stages: Clays, Sandstones.	Sironcha taluka of Gadchiroli district and Achalpur taluka of Amravati district.
Permian	Mangli Beds, Sandstones.	Warora taluka of Chandrapur district.

Age	Geology	Distribution in the districts Covered
(L. Gondwana)	Kamthi series Sandstones, Shales, Coal	Nagpur, Chandrapur and Yavatmal districts.
	Barakar series Sandstone, Shales and Coal	Nagpur, Chandrapur and Yavatmal districts.
Upper Carboniferous	Talchir series	Nagpur, Chandrapur and Yavatmal districts.
Proterozoic	Vindhyan Super Group (Limestones, Shales, Sandstones).	Yavatmal, Nanded and Chandrapur districts
	Cuddapah equivalent Limestones and Shales.	Sironcha Taluka of Gadchiroli district.
	Kaladgi Super Group Sandstones, Shales Conglomerates	Ratnagiri, Sindhudurg and Kolhapur districts.
Precambrian	Sakoli Series, Iron Ore Series	Gadchiroli, Chandrapur, Nagpur and Gondia districts.
	Sausar Series	Nagpur and Bhandara districts.
	Peninsular Basement Complex Gneissic (PGC)	Gadchiroli, Chandrapur, Nagpur, Bhandara and Sindhudurg districts.

PRECAMBRIAN ROCKS

The Precambrian rocks of Maharashtra are as varied and diverse as is found in Peninsular India. They are mostly confined to the north-eastern parts and fringe areas of the State. Most of these rocks are older than 3.5 billion years and are invariably metamorphosed and are grouped in PGC. These are mostly gneisses with enclaves of schists and amphibolites. Gneisses occur in Nagpur, Bhandara, Gondia, Chandrapur, Gadchiroli and Sindhudurg districts. Besides this, the meta sediments belonging to Sausar Series are also exposed in the Nagpur and Bhandara districts and include a variety of rock types such as calcgranulites, calciphyres, quartzites, gneisses, schists and manganese bearing 'gondites'. Structurally, these rocks are intensely folded and faulted as these were subjected to a number of tectonic events. Another group of rocks popularly referred to as the Sakoli Series is exposed in the Gadchiroli, Chandrapur, Nagpur and Gondia districts. These consist of pelitic, psamopelitic and metabasic sediments and include phyllites, schists, amphibolites, quartzites and associated basic intrusives. The Iron Ore Series constitutes an important iron ore bearing formation in Gadchiroli and Sindhudurg districts. The rocks consist of quartzites and Banded Hematite Quartzites with sizeable quantities of exploitable iron ore.

PROTEROZOIC ROCKS

The Basement Gneissic Complex is overlain by the Proterozoic sediments. The limestone rocks equivalent to the Cuddapah Super Group, are exposed in small areas in the southern part of Gadchiroli district. Another equivalent rock formations referred to as Kaladgi Group rest directly on the Precambrian rocks in Sindhudurg and Kolhapur districts. The Kaladgi rocks consist of sandstones and shales and has given rise to important deposits of silica sands. Rocks belonging to this formation occur below the Deccan Trap flows in Kolhapur district. Vast areas in the districts of Nanded, Yavatmal, Chandrapur and Gadchiroli, are occupied by the rocks of the Vindhyan Super Group. They consist of limestones, dolomitic limestones, purple-coloured shales and feldspathic sandstone.

GONDWANA SYSTEM:

The coal bearing Gondwana sediments were deposited in basins formed by the rifting of the Gondwana protocontinent. The sedimentary rocks belonging to the Gondwana system can be divided into two groups namely the Lower Gondwana and the Upper Gondwana. The Lower Gondwana sediments include the Talchir series, the oldest group of rocks followed by Barakar series, Kamthi series and Mangli beds. The Talchir series include serrated boulders and green shales, sandstone, clays and mudstones that were deposited during the glacial period. The Barakar series consists of a thick succession of alternate layers of sandstones and shales with interbedded coal seams. The youngest group of rocks belonging to the lower Gondwana sequence is known as the Mangli beds and consists of conglomerates, grits and sandstones and is exposed in Warora taluka of Chandrapur district. The upper Gondwana sediments include Pachmari, Maleri, Kota and Chikli group and are mainly exposed in Sironcha taluka of Gadchiroli district. Around Bairamghat in Amravati district, the Pachmari group sediments are exposed. They essentially consist of sandstones, shales and clays and include number of plant fossils.

LAMETA AND BAGH BEDS

The rocks formations referred to the Bagh Beds are exposed along the southern bank of Narmada River in Akkalkuwa taluka, Nandurbar district and comprise of siliceous limestones and sandstones. The Lametas comprise essentially of calcareous sandstone, cherty limestones and clays. The Lameta and Bagh Beds are referred to as infra- trappean beds i.e. occurring below the Deccan Traps. These are located at various places and along the fringes of the Deccan Traps near Nagpur and Amravati district.

DECCAN VOLCANIC PROVINCE (DECCAN TRAPS)

It occupies an area of about 2,46,784 sq. km, which is about 82% of the State. The Traps are composed of a thick pile of lava flows seldom separated by flow top breccia or 'red bole'. The individual lava flow varies greatly in thickness from a few metres to as much as 30-35 meters. In the fringe areas i.e. around Mumbai, Nagpur, etc. inter-trappean sediments, which consists of sandstones, shales, marls etc. is exposed between flows. The basaltic flows that constitute the shallow and deeper aquifers present inconsistent and complex hydrogeological pattern. Although climatic, physiographic and rainfall vary widely across the State, the inherent differences in the lava type, their geometry and the superimposing fabric of post-volcanic tectonics are more important locally in contributing to anisotropic nature of the aquifer.

The intrusive dyke swarms occur along two tectonic belts i.e. the West Coast and the Narmada-Tapi River. Most of the dykes are hypabassal. The dykes cut across number of flows and form an important physiographic feature sometimes occurring as ridges (positive feature) and at other places forming linear depressions (negative features). The dykes control groundwater movement and as such are known to be 'carriers' or 'barriers'.

ALLUVIAL DEPOSITS

The alluvial deposits generally occur along the lower reaches of major river valleys. Two well-known alluvial deposits namely, Tapi Valley (districts of Nandurbar, Dhule and Jalgaon) and the Purna Valley (districts of Buldhana, Akola and Amravati) are recognised. These alluvial deposits belong to slightly older period (Quaternary) in geological history than most of the alluvial deposits in the coastal areas of the country. The alluvial deposits in the Tapi and Purna valleys occur in separate, rather, long

narrow basins and occupy a total area of 10,500 sq. km. of which Tapi covers an area of 4100 sq. km and Purna covers 6400 sq. km. On the basis of exploratory drilling, it is known that, these alluvial deposits attained a maximum thickness of about 425 m bgl. Minor alluvial deposits are also known to occur in other parts of the State such as along Bhima, Godavari, Wardha, Wainganga, Penganga rivers and few of their tributaries.

2.8 HYDROGEOLOGY

GROUNDWATER PROVINCES OF MAHARASHTRA

On the basis of geological formations, the State can be divided into the following groundwater provinces: -

- i. Precambrian metamorphic groundwater province
- ii. Proterozoic sedimentary groundwater province
- iii. Gondwana groundwater province
- iv. Deccan Trap volcanic groundwater province
- v. Alluvial groundwater province

Precambrian metamorphic groundwater province

The basement complex rock types such as schists, gneisses, granite, amphibolites and basic intrusives constitute this province. The rocks are very hard and compact and possess practically no primary porosity. However, these are highly weathered and are fractured, sheared and jointed due to numerous tectonic episodes. The secondary porosity is therefore of prime importance in this province. The yield from the wells generally varies from 45 to 80 m³/day and the water level fluctuation varies from 2 to 8 metres. However, the wells located on major lineaments or shear zones have higher yields (100 to 150 m³/day).

Proterozoic sedimentary groundwater province

The compact sediments mainly comprise of Vindhyan and Kaladgi formations. The total area occupied by these sediments is 6,190 sq. km. The Vindhyan comprise of limestones, sandstones and shales. Groundwater occurs in these rocks under phreatic as well as semi-confined conditions. The dug wells piercing the Vindhyan rock types range in depth between 5 and 12 m and static water levels range between 2 and 7 m bgl. The diameters of the wells range between 3 and 5 m. The limestones at places are massive but are generally bedded and exhibit vertical joints. In some places, particularly in Yavatmal and Chandrapur districts they develop 'karst' topography. Geomorphological features such as sink holes, galleries and caverns associated with this topography impart secondary porosity and permeability to this formation. The wells in this area generally sustain a discharge of 50 to 100 m³/day.

Gondwana sedimentary groundwater province

The Gondwana sedimentary rock formations are confined chiefly to the districts of Nagpur, Chandrapur, Yavatmal and Amravati. These sediments occupy a total area of about 4,808 sq. km and comprise of sandstones, shales and clays of varying thickness and degree of compaction. These rocks possess primary porosity. However, due to block faulting and intra-formational faulting and fracturing, secondary porosity is generated within these formations. Occasionally, lenses of pebbles and gravels are also encountered. There are possibilities of encountering confined aquifers in these types of rocks. Few exploratory tube wells drilled by Groundwater Surveys and Development Agency and Central Ground Water Board have indicated a discharge of 100 to 300 m³/day. The dug wells in these types of

rocks vary in depth from 10 to 20 m. The water levels vary from few metres to 8 mbgl. The yield ranges between 50 and 300 m³/day.

Deccan Trap volcanic groundwater province

The Deccan Traps, which occupy about 82% of the total area of the State, is a major groundwater province for consideration and evaluation of groundwater potential in the State. The basalt lava flows are formed as wide spread flows forming extensive plateaus. The entire pile of near horizontal lava flows show variation in their physical character, thereby influencing the aquifer parameters. While considering the occurrence of groundwater in the basaltic hard rocks, which possess very poor primary porosity it is interesting to note that the basaltic lava flows develop vesicular character, especially, in the flow crust. Further, secondary features like weathering, jointing, and shearing develop storage space, which make the basaltic rocks capable of holding and transmitting groundwater. The vesicles, the joint system and inter-flow zones contribute considerably to the yield of the basaltic flow. The yield is considerably affected by other two factors namely, degree of weathering and topographic setting. Weathering increases porosity and permeability and topographic setting affects the movement and discharge of groundwater. Thus a highly weathered vesicular lava flow has good porosity and permeability and proves to be a good aquifer. However, the inter flow horizons such as red boles tend to become clayey and sometimes reduce the aquifer properties. Groundwater in the basaltic aquifers occurs under phreatic and semi-confined conditions. The massive lava flows and thick red-bole layers tend to inhibit vertical movement of groundwater and thus act as confining aquicludes. The productive aquifers when favourably situated receive recharge and groundwater moves down the slopes till it is withdrawn by abstraction structures such as dug wells or natural discharge (spring). The water level and yields of wells are a function of the permeability and thickness of the aquifer encountered. The entire succession of lava flows act as multi-aquifer system. The average depth of wells varies from 9 to 15 m and diameter varies from 4 to 8 m. The range of water level varies from 3 to 7 m and the yield ranges from 75 to 100 m³/day in winter. Wells located in favourable sites have very good yields ranging from 150 to 200 m³/day. In the Deccan traps the low availability of groundwater is attributed to its peculiar geomorphological and geological set up. The lava flows are individually different in their ability to receive, hold as well as to transmit water. The availability and productivity of groundwater in Deccan Trap is entirely dependent in its inherent physical property such as the size and distribution of vesicles, number and spacing of interconnected joints and fractures and degree of weathering.

Alluvial groundwater province

The alluvial deposits in Tapi and Purna valleys are unique in that, they have been deposited in faulted basins. The northern - boundaries of the two basins are faulted and the floors of the basins have sunk to relatively greater depths. The basements have a slope towards north in both the cases. The weathering and erosion of the Satpuras have contributed considerable volume of material in filling up of the two basins. The foothills of the Satpuras have a thick accumulation of pediment deposits commonly referred to as the 'bazada zone'. The thickness of the zone varies considerably but holds tremendous potential as far as artificial recharge to the depleting groundwater is concerned. The alluvial deposits in the basins have attained a maximum thickness of about 400 m at Akot in Akola district of Purna valley and about 300 m at Yawal in Jalgaon district in the Tapi valley. The alluvial sediments in the two basins generally consist of clays, silt, sand, pebbles and boulders. The sand, gravel, boulders etc. occur in one or more beds of 2 to 13 m in thickness, generally within a depth of about 100 m and sometimes even down to the depth of 250 m below the surface. Boulders and gravels sometimes mixed with clays are predominant in the northern part of alluvial area in the Purna basin.

The alluvial deposits in the two areas consist of different type of water bearing horizons. The most important amongst them are the beds of sand, gravel and boulders, as these beds receive recharge, and store and transmit large quantities of groundwater. The alluvial material generally contain one shallow aquifer within a depth of about 20 m and one deep confined aquifer below 30 m. Central Ground Water Board has carried out extensive exploratory drilling in Tapi (57 tube wells) and Purna (78 tube wells) alluvial areas. The depth of these tube wells range from 17 to 322 m bgl. and their yield range is from 5 to 45 lps. The exploratory study has shown that the alluvium is deposited in faulted basin which have prominent northerly tilting basement of the Deccan Trap. The 300 to 350 m thick alluvial deposits can be divided into younger alluvium up to 80 m depth and older alluvium below it. The younger alluvium contains 2 to 4 granular aquifer zones, which have excellent hydrologic parameters. The water levels in open wells vary in depth from 15 to 30 m. In areas bordering Satpura in the north water levels are deeper and the wells are 30 m or more in depth. Most of the existing dug wells yield 100 to 300 m³/day, though in few cases higher yields are observed. Groundwater Surveys and Development Agency has drilled large number of tube wells in these formations especially for drinking water purposes. The chemical quality of groundwater in the aquifer of alluvial deposits is generally good in northern part. However, in Purna alluvial areas the groundwater in shallow aquifers, especially in the southern part of the basin is saline.

2.9 GROUND WATER QUALITY

The chemical quality of groundwater from the shallow basaltic aquifers during 2022 is good (electrical conductivity ~501-1000 µs/cm). In most samples the pH values range from 7.5 to 8.5 indicating the alkaline nature of the groundwater. In Maharashtra, the saline groundwater (electrical conductivity ~2001-3000 µs/cm) are present in three geographically distinct areas viz. the coastal areas of Konkan, the Purna alluvial basin and the upland DPAP areas. The chemical quality of groundwater for deeper aquifers however represents a different picture. Saline groundwater patches (electrical conductivity > 2001µs/cm) are reported from the Konkan coast (Thane, Raigad, Ratnagiri), Purna (Buldana, Akola, Amravati) and the DPAP areas (Pune, Sangli,). The average values of TDS of the samples suggest that the groundwater in the monitoring wells is fresh in nature. It is observed that the Total Dissolved Solids (TDS) of ground water of shallow aquifer in majority of the areas of the state is well within the maximum permissible limits as prescribed by BIS, i.e., below 2000 mg/L. It is also seen that in the plain area of Maharashtra especially in Western Maharashtra, Marathwada and parts of Vidarbha, the TDS of ground water lies mainly in the range of 500–2000 mg/L with some pockets having TDS more than 2000 mg/L. Major parts of Ahmednagar, Akola, Aurangabad, Buldhana, Dhule, Hingoli, Jalna, Nandurbar, Nasik, Nandurbar, Ratnagiri, Sangli, Satara, Solapur and Thane districts are reported to contain higher TDS (>2000 mg/L) in the ground water samples. In plain areas, the residence time for ground water is more, bringing more ions to groundwater through water rock interaction. The increase in TDS in Marathwada region of Maharashtra may be due to high rate of evapotranspiration in the area as it falls under the rain scarcity zone. The Hardness of groundwater range between 100 to 500 mg/lit which is suitable for drinking purposes. The fluoride concentration in groundwater from the Precambrian basement rocks and Proterozoic sediments are above prescribed limits of BIS drinking water standard (>1.5 mg/l). Such occurrences have been reported from districts such as Chandrapur, Nagpur, Gadchiroli, Yavatmal, Nanded, Bhandara and Sindhudurg However, it is to mention here that these are treated as point sources and not applicable to the entire watershed.

CHAPTER 3

3. GROUND WATER RESOURCE ESTIMATION METHODOLOGY, 2015

The ground water assessment of the country is being carried out jointly by State Ground Water Departments i.e., Groundwater Surveys and Development Agency (GSDA) and Central Ground Water Board (CGWB) based on “Ground Water Estimation Methodology, 1997” (GEC-97). Previous such joint exercises based on GEC-97 Methodology was carried out in 2004, 2009, 2011 and 2013. A number of changes have taken place since 1997 and with this background, the Ministry of Water Resources, River Development & Ganga Rejuvenation has constituted a committee headed by Chairman, CGWB to review and revise the existing GEC-97 Methodology and to incorporate new advancements/practices/tools so as to suggest a new methodology known as “*Ground Water Estimation Methodology, 2015*” (GEC-2015 Methodology). The Committee has submitted a report on “Ground Water Estimation Methodology, 2015” incorporating refinement in the assessment methodology, database used for estimation and alternative approach for assessment involving Advanced Technology. The revised methodology as recommended has incorporated number of changes compared to the recommendations of Ground Water Estimation Committee- 1997.

3.1 APPROACH OF GEC-2015

The revised methodology GEC 2015 recommends aquifer wise ground water resource assessment. Ground water resources have two components—Replenishable ground water resources or Dynamic ground water resources and In-storage resources or Static resources. GEC- 2015 recommends estimation of Replenishable and in-storage ground water resources for both unconfined and confined/ semi-confined aquifers. Wherever the aquifer geometry has not been firmly established for the unconfined aquifer, the in-storage ground water resources have to be assessed in the alluvial areas up to the depth of bed rock or 300m whichever is less. In case of hard rock aquifers, the depth of assessment would be limited to 100m. In case of confined aquifers, if it is known that ground water extraction is being taken place from this aquifer, the dynamic as well as in-storage resources are to be estimated. If it is firmly established that there is no ground water extraction from this confined aquifer, then only in-storage resources of that aquifer have to be estimated.

3.2 GROUND WATER ASSESSMENT UNIT AND ITS SUB UNITS

This methodology recommends aquifer wise ground water resource assessment. An essential requirement for this is to demarcate lateral as well as vertical extent and disposition of different aquifers. A watershed with well-defined hydrological boundaries is an appropriate unit for ground water resource estimation if the principal aquifer is other than alluvium. Ground water resources worked out on watershed as a unit, may be apportioned and presented on administrative units (block/ taluka/ mandal/ firka).

It is recommended that ground water recharge may be estimated for the entire assessment unit. Out of the total geographical area of the unit, hilly areas wherever slope is greater than 20%, are to be identified and subtracted as these areas have more runoff than infiltration. The hilly areas wherever slope is more than 20% may be demarcated using DEM data and geomorphological maps. Apart from this it is also important that the areas where the quality of ground water is beyond the usable limits (for drinking water in particular) in terms of salinity is to be identified and handled separately. This methodology recommends that after the assessment is done, a quality flag may be added to the assessment unit for parameters salinity, fluoride and arsenic.

The ground water resource beyond the permissible quality limits in terms of the salinity has to be computed separately. The remaining area after excluding the area with poor ground water quality is to be delineated as follows:

- (a) Non-command areas which do not come under major/medium surface water irrigation schemes.
- (b) Command areas which come under major/medium surface water irrigation schemes which are actually supplying water.

3.3 GROUND WATER RESOURCES OF AN ASSESSMENT UNIT

The ground water resources of any assessment unit is the sum of the total ground water availability in the principal aquifer (mostly unconfined aquifer) and the total ground water availability of semi-confined and confined aquifers existing in that assessment unit. The total ground water availability of any aquifer is the sum of dynamic ground water resources and the in-storage or static resources of the aquifer.

3.4 GROUND WATER ASSESSMENT OF UNCONFINED AQUIFER

Assessment of ground water resources includes the assessment of dynamic and in-storage ground water resources. The development planning should mainly depend on dynamic resource only as it gets replenished every year. Changes in static or in-storage resources reflect impacts of ground water mining. Such resources may not be replenishable annually and may be allowed to be extracted only during exigencies with proper recharge planning in the succeeding excess rainfall years.

Assessment of Dynamic Ground Water Resources

The methodology for ground water resources estimation is based on the principle of water balance as given below –

$$\text{Inflow} - \text{Outflow} = \text{Change in Storage (of an aquifer)} \quad (1)$$

Equation 1 can be further elaborated as –

$$\Delta S = R_{RF} + R_{STR} + R_C + R_{SWI} + R_{GWI} + R_{TP} + R_{WCS} \pm VF \pm LF - GE - T - E - B$$

(2)

Where,

- ΔS – Change in storage
- R_{RF} – Rainfall recharge
- R_{STR} – Recharge from stream channels
- R_C – Recharge from canals
- R_{SWI} – Recharge from surface water irrigation
- R_{GWI} – Recharge from ground water irrigation
- R_{TP} – Recharge from Tanks & Ponds
- R_{WCS} – Recharge from water conservation structures
- VF – Vertical inter aquifer flow
- LF – Lateral flow along the aquifer system (through flow)
- GE – Ground Water Extraction
- T – Transpiration
- E – Evaporation
- B – Base flow

It is preferred that all the components of water balance equation should be estimated in an assessment unit.

Rainfall Recharge

It is recommended that ground water recharge should be estimated on ground water level fluctuation method and rainfall infiltration factor method during monsoon season and the rainfall recharge during non-monsoon season may be estimated using rainfall infiltration factor method only.

Ground water level fluctuation method

The ground water level fluctuation method is to be used for assessment of rainfall recharge in the monsoon season. The ground water balance equation is given by

$$\Delta S = R_{RF} + R_{STR} + R_C + R_{SWI} + R_{GWI} + R_{TP} + R_{WCS} \pm VF \pm LF - GE - T - E - B \quad (3)$$

Where,

- ΔS – Change in storage
- R_{RF} – Rainfall recharge
- R_{STR} – Recharge from stream channels
- R_C – Recharge due to Canals
- R_{SWI} – Recharge from surface water irrigation (Lift Irrigation)
- R_{GWI} – Recharge from ground water irrigation
- R_{TP} – Recharge from tanks & ponds
- R_{WCS} – Recharge from water conservation structures
- VF – Vertical inter aquifer flow
- LF – Lateral flow along the aquifer system (through flow)
- GE – Ground water Extraction
- T – Transpiration
- E – Evaporation
- B – Base flow

This change in storage can be estimated using the following equation:

$$\Delta S = \Delta h * A * SY \quad (4)$$

Where

- ΔS – Change in storage
- Δh – rise in water level in the monsoon season
- A – Area for computation of recharge
- Sy – Specific Yield

Substituting the expression in equation 4 for increase in storage i.e. ΔS in terms of water level fluctuation and specific yield, the equation 3 becomes,

$$R_{RF} = \Delta h \times SY \times A - R_{STR} - R_C - R_{SWI} - R_{GWI} - R_{TP} - R_{WCS} \pm VF \pm LF + GE + T + E + B \quad (5)$$

The recharge calculated from equation 5 gives the rainfall recharge for the particular monsoon season. This rainfall recharge is specific to a particular monsoon season for the associated monsoon season rainfall. This estimate is to be normalised for the normal monsoon season rainfall as per the procedure indicated below.

Normalization of Rainfall Recharge

Let R_i be the rainfall recharge and r_i be the associated rainfall. The subscript i takes values 1 to N where N is the number of years for which data is available. This should be at least 5. The rainfall recharge, R_i is obtained as per equation 5 for which the normalization is to be done using any of the following two procedures. This normalisation procedure is to be carried out for obtaining the rainfall recharge corresponding to the normal monsoon season rainfall. Let $r(\text{normal})$ be the normal monsoon season rainfall obtained as the average of recent 30 to 50 years of monsoon season rainfall. Two methods are possible for the normalisation procedure.

The first method is based on a linear relationship between recharge and rainfall of the form

$$R = ar \quad (6)$$

Where,

R = Rainfall recharge during monsoon season

r = Monsoon season rainfall

a = constant

The second method is also based on a linear relation between recharge and rainfall. However, this linear relationship is of the form,

$$R = ar + b \quad (7)$$

Where,

R = Rainfall recharge during monsoon season

r = Monsoon season rainfall

a and b = constants.

The rainfall recharge during monsoon season for normal monsoon rainfall condition is computed as below:

$$R_{rf} (normal) = a \times r (normal) \quad (8)$$

Or

$$R_{rf} (normal) = a \times r(normal) + b \quad (9)$$

Rainfall Infiltration Factor method

Recharge from rainfall is estimated by using the following relationship –

$$R_{rf} = RFIF * A * (R - a)/1000 \quad (10)$$

Where,

R_{rf} = Rainfall recharge in ham

A = Area in Hactares

RFIF = Rainfall Infiltration Factor

R = Rainfall in mm

a = Minimum threshold value above which rainfall induces ground water recharge in mm

The threshold limit of minimum and maximum rainfall event which can induce recharge to the aquifer is to be considered while estimating ground water recharge using rainfall infiltration factor method. It is suggested that 10% of Normal annual rainfall may be taken as minimum rainfall threshold and 3000 mm as maximum rainfall limit. The same recharge factor may be used for both monsoon and non-monsoon rainfall, with the condition that the recharge due to non-monsoon rainfall may be taken as zero, if the normal rainfall during the non-monsoon season is less than 10% of normal annual rainfall.

Percent Deviation

After computing the rainfall recharge for normal monsoon season rainfall using the ground water level fluctuation method and rainfall infiltration factor method these two estimates have to be

compared with each other. A term, Percent Deviation (PD) which is the difference between the two expressed as a percentage of the later is computed as

$$PD = \frac{R_{rf} (normal, wtfm) - R_{rf} (normal, rfm)}{R_{rf} (normal, rfm)} \times 100 \quad (11)$$

Where,

R_{rf} (normal, wlfm) = Rainfall recharge for normal monsoon season rainfall estimated by the ground water level fluctuation method

R_{rf} (normal, rfm) = Rainfall recharge for normal monsoon season rainfall estimated by the rainfall infiltration factor method

The rainfall recharge for normal monsoon season rainfall is finally adopted as per the criteria given below:

- If PD is greater than or equal to -20%, and less than or equal to +20%, R_{rf} (normal) is taken as the value estimated by the ground water level fluctuation method.
- If PD is less than -20%, R_{rf} (normal) is taken as equal to 0.8 times the value estimated by the rainfall infiltration factor method.
- If PD is greater than +20%, R_{rf} (normal) is taken as equal to 1.2 times the value estimated by the rainfall infiltration factor method.

Recharge from other Sources

Recharge from other sources constitutes recharges from canals, surface water irrigation, ground water irrigation, tanks & ponds and water conservation structures in command areas where as in non-command areas it constitutes the recharge due to surface water irrigation, ground water irrigation, tanks & ponds and water conservation structures.

Recharge from Canals: Recharge due to canals is to be estimated based on the following formula:

$$R_C = WA * SF * Days \quad (12)$$

Where:

R_C = Recharge from Canals

WA = Wetted Area = Wetted Perimeter X Length of Canal Reach.

SF = Seepage Factor

Days = Number of Canal Running Days.

Recharge from Surface Water Irrigation: Recharge due to applied surface water irrigation, either by means of canal outlets or by lift irrigation schemes is to be estimated based on the following formula:

$$R_{SWI} = AD * Days * RFF \quad (13)$$

Where:

R_{SWI} = Recharge due to applied surface water irrigation

AD = Average Discharge

Days = Number of days water is discharged to the Fields

RFF = Return Flow Factor

Recharge from Ground Water Irrigation: Recharge due to applied ground water irrigation is to be estimated based on the following formula:

$$R_{GWI} = GE_{IRR} * RFF \quad (14)$$

Where:

R_{GWI} = Recharge due to applied ground water irrigation

GE_{IRR} = Ground Water Extraction for Irrigation

RFF= Return Flow Factor

Recharge due to Tanks & Ponds: Recharge due to Tanks & Ponds is to be estimated based on the following formula:

$$R_{TP} = AWSA * N * RF \quad (15)$$

Where:

R_{TP} = Recharge due to Tanks & Ponds

AWSA= Average Water Spread Area

N=Number of days Water is available in the Tank/Pond

RF= Recharge Factor

Recharge due to Water Conservation Structures: Recharge due to Water Conservation Structures is to be estimated based on the following formula:

$$R_{WCS} = GS * RF \quad (16)$$

Where:

R_{WCS} = Recharge due to Water Conservation Structures

GS= Gross Storage = Storage Capacity multiplied by number of fillings.

RF= Recharge Factor

Lateral flow along the aquifer system (Through flow)

If the area under consideration is a watershed, the lateral flow across boundaries can be considered as zero. If there is inflow and outflow across the boundary, theoretically, the net inflow may be calculated using Darcy law, by delineating the inflow and outflow sections of the boundary. Besides such delineation, the calculation also requires estimate of transmissivity and hydraulic gradient across the inflow and outflow sections.

Base flow and Stream Recharge

If stream gauge stations are located in the assessment unit, the base flow and recharge from streams can be computed using Stream Hydrograph Separation method, Numerical Modelling and Analytical solutions. If the assessment unit is a watershed, a single stream monitoring station at the mouth of the watershed can provide the required data for the calculation of base flow.

Base flow assessment and Stream recharge should be carried out in consultation with Central Water Commission in order to avoid any duplicity in the estimation of total water availability in a river basin.

Vertical Inter Aquifer Flow

This can be estimated provided aquifer geometry and aquifer parameters are known. This can be calculated using the Darcy's law if the hydraulic heads in both aquifers and the hydraulic conductivity and thickness of the aquitard separating both the aquifers are known.

Evaporation and Transpiration

Evaporation can be estimated for the aquifer in the assessment unit if water levels in the aquifer are within the capillary zone. It is recommended to compute the evaporation through field studies. If field studies are not possible, for areas with water levels within 1.0 mbgl, evaporation can be estimated using the evaporation rates available for other adjoining areas. If depth to water level is more than 1.0m bgl, the evaporation losses from the aquifer should be taken as zero.

Transpiration through vegetation can be estimated if water levels in the aquifer are within the maximum root zone of the local vegetation. It is recommended to compute the transpiration through field studies. Even though it varies from place to place depending on type of soil & vegetation, in the absence of field studies the following estimation can be followed. If water levels are within 3.5m bgl, transpiration can be estimated using the transpiration rates available for other areas. If it is greater than 3.5m bgl, the transpiration should be taken as zero.

Recharge/ Accumulations during Monsoon Season

The sum of normalized monsoon rainfall recharge and the recharge from other sources and lateral and vertical flows into the sub unit and stream inflows during monsoon season is the total recharge/ accumulation during monsoon season for the sub unit. Similarly, this is to be computed for all the sub units available in the assessment unit.

Recharge/ Accumulations during Non-Monsoon Season

The rainfall recharge during non-monsoon season is estimated using rainfall infiltration factor Method only when the non-monsoon season rainfall is more than 10% of normal annual rainfall. The sum of non-monsoon rainfall recharge and the recharge from other sources and lateral and vertical flows into the sub unit and stream inflows during non-monsoon season is the total recharge/ accumulation during non-monsoon season for the sub unit. Similarly, this is to be computed for all the sub units available in the assessment unit.

Total Annual Ground Water Recharge

The sum of the recharge/ accumulations during monsoon and non-monsoon seasons is the total annual ground water recharge/ accumulations for the sub unit. Similarly, this is to be computed for all the sub units available in the assessment unit.

Annual Extractable Ground Water Resource (EGR)

The Total Annual Ground Water Recharge cannot be utilised for human consumption, since ecological commitments need to be fulfilled, before the extractable resources is defined. The National Water Policy, 2012 stresses that the ecological flow of rivers should be maintained. Therefore, ground water base flow contribution limited to the ecological flow of the river should be determined which will be deducted from Annual Ground Water Recharge to determine Annual Extractable Ground Water Resources (EGR). The ecological flows of the rivers are to be determined in consultation with Central Water Commission and other concerned river basin agencies.

In case base flow contribution to the ecological flow of rivers is not determined then following assumption is to be followed. If the rainfall recharge is assessed using water level fluctuation method this will be 5% of the annual recharge and if it is assessed using rainfall infiltration factor method, it will be 10% of the annual recharge. The balance will account for Annual Extractable Ground Water Resources (EGR).

Estimation of Ground Water Extraction

Ground water draft or extraction is to be assessed as follows.

$$GE_{ALL} = GE_{IRR} + GE_{DOM} + GE_{IND} \quad (17)$$

Where,

GE_{ALL} =Ground water extraction for all uses

GE_{IRR} = Ground water extraction for irrigation
 GE_{DOM} = Ground water extraction for domestic uses
 GE_{IND} = Ground water extraction for industrial uses

The single largest component of the ground water balance equation in large regions of India is the ground water extraction and the precise estimation of ground water extraction is riddled with uncertainties.

Ground Water Extraction for Irrigation (GE_{IRR}): The Ground Water Extraction for Irrigation is to be assessed employing at least two of the three methods recommended for estimation of ground water extraction for irrigation. The methods for estimation of ground water extraction are as follows.

Unit Draft Method: – In this method, season-wise unit draft of each type of well in an assessment unit is estimated. The unit draft of different types (eg. Dug well, Dug cum bore well, shallow tube well, deep tube well, bore well etc.) is multiplied with the number of wells of that particular type to obtain season-wise ground water extraction by that particular structure. This method is being widely practiced in the country. There are several sources which maintain records on well census. These include Minor Irrigation Census conducted by MoWR, RD, GR, Government of India, and data maintained at the Tahsil level. It is recommended that a single source of well census should be maintained for resources computation at all India level. Minor Irrigation Census of MoWR, RD, GR would be the preferred option.

Crop Water Requirement Method: – For each crop, the season-wise net irrigation water requirement is determined. This is then multiplied with the area irrigated by ground water abstraction structures. The database on crop area is obtained from Revenue records in Tahsil office, Agriculture Census and also by using Remote Sensing techniques.

Power Consumption Method: –Ground water extraction for unit power consumption (electric) is determined. Extraction per unit power consumption is then multiplied with number of units of power consumed for agricultural pump sets to obtain total ground water extraction for irrigation.

Ground Water Extraction for Domestic Use (GE_{DOM}): There are several methods for estimation of extraction for domestic use (GE_{DOM}). Some of the commonly adopted methods are described here.

Unit Draft Method: – In this method, unit draft of each type of well is multiplied by the number of wells used for domestic purpose to obtain the domestic ground water extraction.

Consumptive Use Method: – In this method, population is multiplied with per capita consumption usually expressed in litre per capita per day (lpcd). It can be expressed using following equation.

$$GE_{DOM} = \text{Population} \times \text{Consumptive Requirement} \times L_g \quad (18)$$

Where,

L_g = Fractional Load on Ground Water for Domestic Water Supply

The Load on Ground water can be obtained from the Information based on Civic water supply agencies in urban areas.

Ground water Extraction for Industrial use (GE_{IND}): The commonly adopted methods for estimating the extraction for industrial use are as below:

Unit Draft Method: - In this method, unit draft of each type of well is multiplied by the number of wells used for industrial purpose to obtain the industrial ground water extraction.

Consumptive Use Pattern Method: – In this method, water consumption of different industrial units is determined. Number of Industrial units which are dependent on ground water are multiplied with unit water consumption to obtain ground water extraction for industrial use.

$$GE_{IND} = \text{Number of industrial units} \times \text{Unit Water Consumption} \times L_g \quad (19)$$

Where,

L_g = Fractional load on ground water for industrial water supply

The load on ground water for industrial water supply can be obtained from water supply agencies in the Industrial belt. Other important sources of data on ground water extraction for industrial uses are - Central Ground Water Authority, State Ground Water Authority, National Green Tribunal and other Environmental Regulatory Authorities.

Ground water extraction obtained from different methods need to be compared and based on field checks, the seemingly best value may be adopted. At times, ground water extraction obtained by different methods may vary widely. In such cases, the value matching the field situation should be considered.

Stage of Ground Water Extraction

The stage of ground water extraction is defined by,

$$\text{Stage of Ground Water Extraction}(\%) = \frac{\text{Existing Gross Ground Water Extraction of all uses}}{\text{Annual Extractable Ground Water Resources}} \times 100 \quad (20)$$

The existing gross ground water extraction for all uses refers to the total of existing gross ground water extraction for irrigation and all other purposes. The stage of ground water extraction should be obtained separately for command areas, non-command areas and poor ground water quality areas.

Validation of Stage of Ground Water Extraction

The assessment based on the stage of ground water extraction has inherent uncertainties. The estimation of ground water extraction is likely to be associated with considerable uncertainties as it is based on indirect assessment using factors such as electricity consumption, well census and area irrigated from ground water. The denominator in equation 20, namely Annual Extractable Ground Water Resources also has uncertainties due to limitations in the assessment methodology, as well as uncertainties in the data. In view of this, it is desirable to validate the ‘Stage of Ground Water Extraction’ with long term trend of ground water levels.

Long term water level trends are to be prepared for a minimum period of 10 years for both pre-monsoon and post-monsoon period. The water level trend would be average water level trend as obtained from the different observation wells in the area.

If the ground water resource assessment and the trend of long term water levels contradict each other, this anomalous situation requires a review of the ground water resource computation, as well as the reliability of water level data. The mismatch conditions are enumerated below.

SOGWE	Ground Water Level Trend	Remarks
≤70%	Significant decline in trend in both pre-monsoon and post-monsoon	Not acceptable and needs reassessment
>100%	No significant decline in both pre-monsoon and post-monsoon long term trend	Not acceptable and needs reassessment

Categorization of Assessment Units Based on Quantity: The categorization based on status of ground water quantity is defined by Stage of Ground Water Extraction as given below:

Stage of Ground Water Extraction	Category
≤70%	Safe
> 70% and ≤90%	Semi-Critical
> 90% and ≤100%	Critical
> 100%	Over Exploited

Quality Tag

If any of the three quality hazards in terms of Arsenic, Fluoride and Salinity are encountered in the assessment sub unit in mappable units on 1:50000 scale, the assessment sub unit may be tagged with the particular quality hazard.

Allocation of Ground Water Resource for Utilisation

The Annual Extractable Ground Water Resources are to be apportioned between domestic, industrial and irrigation uses. Among these, as per the National Water Policy, requirement for domestic water supply is to be accorded priority. This requirement has to be based on population as projected to the year 2025, per capita requirement of water for domestic use, and relative load on ground water for urban and rural water supply. The estimate of allocation for domestic water requirement may vary from one sub unit to the other in different states. In situations where adequate data is not available to make this estimate, the following empirical relation is recommended.

$$\text{Alloc} = 22 \times N \times L_g \text{ mm per year} \quad (21)$$

Where,

Alloc= Allocation for domestic water requirement

N = population density in the unit in thousands per sq. km.

L_g = fractional load on ground water for domestic water supply (≤ 1.0)

In deriving equation 21, it is assumed that the requirement of water for domestic use is 60 lpd per head. The equation can be suitably modified in case per capita requirement is different. If by chance, the estimation of projected allocation for future domestic needs is less than the current domestic extraction due to any reason, the allocation must be equal to the present-day extraction. It can never be less than the present-day extraction as it is unrealistic.

Net Annual Ground Water Availability for Future Use

The water available for future use is obtained by deducting the allocation for domestic use and current extraction for Irrigation and Industrial uses from the Annual Extractable Ground Water Recharge. The resulting ground water potential is termed as the net annual ground water availability for future use. The Net annual ground water availability for future use should be calculated separately for non-command areas and command areas. As per the recommendations of the R&D Advisory committee, the ground water available for future use can never be negative. If it becomes negative, the

future allocation of Domestic needs can be reduced to current extraction for domestic use. Even then if it is still negative, then the ground water available for future uses will be zero.

ADDITIONAL POTENTIAL RESOURCES UNDER SPECIFIC CONDITIONS

Potential Resource Due to Spring Discharge: Spring discharge constitutes an additional source of ground water in hilly areas which emerges at the places where ground water level cuts the surface topography. Even though, the Spring Discharge is a form of 'Annual Extractable Ground Water Recharge', It is considered as a potential resource because of the limited data available as on today. Spring discharge measurement is to be carried out by volumetric measurement of discharge of the springs. Spring discharges multiplied with time in days of each season will give the quantum of spring resources available during that season. The committee recommends that in hilly areas with substantial potential of spring discharges, the discharge measurement should be made at least 4 times a year in parity with the existing water level monitoring schedule.

$$\text{Potential ground water resource due to springs} = Q \times \text{No of days} \quad (22)$$

Where,

Q = Spring Discharge

No of days= No of days spring yields.

Potential Resource in Waterlogged and Shallow Water Table Areas: In the area where the ground water level is less than 5m below ground level or in waterlogged areas, the resources up to 5m below ground level are potential and would be available for development in addition to the annual recharge in the area. It is therefore recommended that in such areas, ground water resources may be estimated up to 5m bgl only assuming that where water level is less than 5m bgl, the same could be depressed by pumping to create space to receive recharge from natural resources. It is further evident that this potential recharge would be available mostly in the shallow water table areas which would have to be demarcated in each sub-basin/ watershed/ block/ taluka/ mandal/ Firka. The computation of potential resource of the ground water reservoir can be done by adopting the following equation:

$$\text{Potential ground water resource in shallow water table areas} = (5-D) \times A \times S_Y \quad (23)$$

Where,

D= Depth to water table below ground surface in pre-monsoon period in shallow aquifers.

A= Area of shallow water table zone.

S_Y = Specific Yield

Potential Resource in Flood Prone Areas: Ground water recharge from a flood plain is mainly the function of the following parameters-

- Areal extent of flood plain
- Retention period of flood
- Type of sub-soil strata and silt charge in the river water which gets deposited and controls seepage

Since collection of data on all these factors is time taking and difficult, in the meantime, the potential resource from flood plain may be estimated on the same norms as for ponds, tanks and lakes. This has to be calculated over the water spread area and only for the retention period using the following formula.

$$\text{Potential ground water resource in Flood Prone Areas} = 1.4 \times N \times A/1000 \quad (24)$$

Where,

N = No of Days Water is Retained in the Area

A = Flood Prone Area

Apportioning of Ground Water Assessment from Watershed to Development Unit:

Where the assessment unit is a watershed, there is a need to convert the ground water assessment in terms of an administrative unit such as block/ taluka/ mandal/ firka. This may be done as follows.

A block may comprise of one or more watersheds, in part or full. First, the ground water assessment in the subareas, command, non-command and poor ground water quality areas of the watershed may be converted into depth unit (mm), by dividing the annual recharge by the respective area. The contribution of this subarea of the watershed to the block, is now calculated by multiplying this depth with the area in the block occupied by this sub-area. This procedure must be followed to calculate the contribution from the sub-areas of all watersheds occurring in the block, to work out the total ground water resource of the block.

The total ground water resource of the block should be presented separately for each type of sub-area, namely for command areas, non-command areas and poor ground water quality areas, as in the case of the individual watersheds.

Assessment of In-Storage Ground Water Resources or Static Ground Water Resources

The quantum of ground water available for development is usually restricted to long term average recharge or dynamic resources. For sustainable ground water development, it is necessary to restrict it to the dynamic resources. Static or in-storage ground water resources could be considered for development during exigencies that also for drinking water purposes. It is also recommended that no irrigation development schemes based on static or in-storage ground water resources be taken up at this stage.

The computation of the static or in-storage ground water resources may be done after delineating the aquifer thickness and specific yield of the aquifer material. The computations can be done as follows: -

$$SGWR = A * (Z_2 - Z_1) * S_Y \quad (25)$$

Where,

SGWR = Static or in-storage Ground Water Resources

A = Area of the Assessment Unit

Z₂ = Bottom of Unconfined Aquifer

Z₁ = Pre-monsoon water level

S_Y = Specific Yield in the In storage Zone

Assessment of Total Ground Water Availability in Unconfined Aquifer

The sum of Annual Exploitable Ground Water Resource and the in storage ground water resources of an unconfined aquifer is the Total Ground Water Availability of that aquifer.

3.5 GROUND WATER ASSESSMENT OF CONFINED AQUIFER SYSTEM

Assessment of ground water resources of confined aquifers assumes crucial importance, since over-exploitation of these aquifers may lead to far more detrimental consequences than to those of shallow unconfined aquifers.

Most of the storage in confined aquifer is associated with compressibility of the aquifer matrix and compressibility of water. Once the piezometric head reaches below the top confining bed, it behaves like an unconfined aquifer and directly dewater the aquifer and there is a possibility of damage to the aquifer as well as topography. Hence ground water potential of a confined aquifer is nothing but the water available for use without damaging the aquifer. Hence the resources available under pressure are

only considered as the ground water potential. The quantity of water released in confined aquifer due to change in pressure can be computed between piezometric head (h_t) at any given time 't' and the bottom of the top confining layer (h_0) by using the following equation.

$$Q_p = SA\Delta h = SA (h_t - h_0) \quad (26)$$

Where,

Q_p = Ground Water Potential of Confined Aquifer

S = Storativity

A = Areal extent of the confined aquifer

Δh = Change in Piezometric head

h_t = Piezometric head at any particular time

h_0 = Bottom of the top Confining Layer

If any development activity is started in the confined aquifer, then there is a need to assess the dynamic as well as in storage resources of the confined aquifer. To assess the ground water resources of the confined aquifer, there is a need to have sufficient number of observation wells tapping exclusively that particular aquifer and proper monitoring of the piezometric heads is also needed.

To assess the dynamic ground water resources of the confined aquifer the following equation can be used with the pre and post monsoon piezometric heads of the particular aquifer.

$$Q_D = SA\Delta h = SA (h_{POST} - h_{PRE}) \quad (27)$$

Where,

Q_D = Dynamic Ground Water Resource of Confined Aquifer (m^3)

S = Storativity

A = Areal extent of the confined aquifer (m^2)

Δh = Change in Piezometric head (m)

h_{post} = Piezometric head during post-monsoon period (m amsl)

h_{PRE} = Piezometric head during pre-monsoon period (m amsl)

In storage Ground Water Resources of Confined Aquifer

For assessing the in-storage ground water potential of a confined aquifer, one has to compute the resources between the pre-monsoon piezometric head and bottom of the top confining layer. That can be assessed using the following formula:

$$Q_I = SA\Delta h = SA (h_{PRE} - h_0) \quad (28)$$

Where,

Q_I = In storage Ground Water Resource of Confined Aquifer (m^3)

S = Storativity

A = Areal extent of the confined aquifer (m^2)

Δh = Change in Piezometric head (m)

h_0 = Bottom level of the top confining layer (m amsl)

h_{PRE} = Piezometric head during pre-monsoon period (m amsl)

If the confined aquifer is not being exploited for any purpose, the dynamic and static resources of the confined aquifer need not be estimated separately. Instead the in storage of the aquifer can be computed using the following formula.

$$Q_p = SA\Delta h = SA (h_{POST} - h_0) \quad (29)$$

Where,

Q_p = In storage Ground Water Resource of the confined aquifer or the Quantity of water under pressure (m^3)
 S = Storativity
 A = Areal extent of the confined aquifer (m^2)
 Δh = Change in Piezometric head (m)
 H_{POST} = Piezometric head during post-monsoon period (m amsl)
 h_0 = Bottom of the Top Confining Layer (m amsl)

The calculated resource includes small amount of dynamic resource of the confined aquifer also, which replenishes every year. But to make it simpler this was also computed as part of the static or in-storage resource of the confined aquifer.

Assessment of Total Ground Water Availability of Confined Aquifer

If the confined aquifer is being exploited, the Total Ground Water Availability of the confined aquifer is the sum of Dynamic Ground Water Resources and the in-storage ground water resources of that confined aquifer. Whereas if it is not being exploited, the Total Ground Water Availability of the confined aquifer comprises of only one component i.e. the in-storage of that confined aquifer.

3.6 GROUND WATER ASSESSMENT OF SEMI-CONFINED AQUIFER SYSTEM

The Assessment of Ground Water Resources of a semi-confined aquifer has some more complications. Unless and until, it is well studied that the recharge to this is not computed either in the over lying unconfined aquifer or underlying/overlying semi confined aquifers, it should not be assessed separately. If it is assessed separately, there is a possibility of duplication of estimating the same resource by direct computation in one aquifer and as leakage in the other aquifer. As it is advisable to under estimate rather than to overestimate the resources, it is recommended not to assess these resources separately as long as there is no study indicating its non-estimation. If it is found through field studies that the resources are not assessed in any of the aquifers in the area, these resources are to be assessed following the methodology similar to that used in assessing the resources of Confined aquifers.

3.7 TOTAL GROUND WATER AVAILABILITY OF AN AREA

The Total Ground Water Availability in any area is the Sum of Dynamic Ground Water Resources, the static/in-storage ground water resources in the unconfined aquifer and the dynamic and In-storage resources of the Confined aquifers and semi-confined aquifers in the area.

TERMINOLOGY CHANGE There are minor changes in the terminology used in GEC-2015 methodology and the corresponding changes for the terms have been tabulated below:

GEC- 97 Methodology	GEC-2015 methodology
Annual Replenishable Resources	Total Annual Groundwater Recharge
Net Groundwater Availability	Annual Extractable Groundwater Resources
Groundwater Draft	Groundwater Extraction
Annual Groundwater Draft for all uses	Current Annual Groundwater Extraction for all uses
Projected Demand for Domestic and Industrial uses up to 2025	Annual ground water allocation for domestic water supply as on 2025
Groundwater Availability for future irrigation	Net Annual Groundwater Availability for future Use
Stage of Groundwater Development	Stage of Ground Water Extraction

CHAPTER 4

4. PROCEDURE FOLLOWED FOR GROUNDWATER ESTIMATION 2023

4.1 DATA SOURCE

4.1.1 Area

Since 1973, watershed is being used as a unit of assessment in the State irrespective of the Methodology. The areas of the watersheds have been demarcated and computed by Groundwater Surveys and Development Agency. The command areas of the Irrigation Project as notified by Water Resources Department, GoM have been used in this assessment. The poor-quality area within a village as notified by the Revenue Department has been considered in this assessment. This data base is used for sub-dividing the assessment unit into command, non-command and poor-quality area.

4.1.2 Well Census

The IVth Minor Irrigation well census data have been procured from the Chief Engineer, Minor Irrigation Department as suggested by GoI. The IVth Minor Irrigation well census data containing irrigation wells/bore wells/tube wells, or the revenue data collected from local authorities, whichever was higher have been used in the draft calculations. Similarly, the Revenue well data have been cross verified with the number of electric connections registered with the Maharashtra State Electricity Distribution Company.

Presently, instead of dug wells, bore wells are being drilled on large scale in the State, tapping shallow and semi-confined aquifers. Very few bore wells are tapping deeper aquifer, but their details are not available. Hence the irrigation bore wells have been considered for the draft purpose.

There are limitations in the well census data, as their physical numbers are available; but their draft or abstraction details are not available with any of the organizations in the State. Hence, based on the hydrogeology and crop water requirement for the average cropping pattern of the watershed, the watershed wise unit draft has been worked out for the irrigation dug wells and borewells. Similarly, based on the hydrogeology, drinking water requirements and the pumping device, the unit draft, for the dug well and borewell, has been worked out.

4.1.3 Canals, Tanks & Ponds

The data base related to surface water bodies, canals, command area, number of rotations, and volume of water released into the canals etc have been collected or procured from the Water Resources, Water Conservation and Minor Irrigation Department for the year 2022.

4.1.4 Water Conservation Structures

The Directorate of Soil Conservation and Watershed Development Department is monitoring and implementing the water conservation measures in the State. The water conservation structures completed up to 2022 in the State have been considered. Apart from the WCS data, data from Agriculture, Minor Irrigation-Zila Parishad and GSDA is also utilized.

Apart from the conventional water conservation structures, **recharge shafts** constructed under various schemes have also been included as water conservation measures. Since recharge shafts enhance the general recharge capacity of the water conservation structures such as Cement Nala Bund, it adds on the induced recharge.

Each recharge shaft is estimated to add recharge of 100 cum (0.01 Ham). The unit recharge from a shaft is estimated based on the average dimension of the collection trench (10mX5mX2m). Studies on Managed Aquifer Recharge as documented in DFID report, CR/06/107N, British Geological

Survey, 2006 are also considered while establishing the recharge quantum due to recharge shaft. A Case study from Wardha district also indicates about a recharge of 400 cum (0.04 Ham) from a Recharge Shaft.

4.1.5 Cropping Pattern

The village wise cropping data and irrigated agriculture data, as on 2022, as received from district offices of the State Agriculture department have been used for the computations of irrigation return flow and for cross verification of groundwater draft.

4.1.6 Rainfall

The district revenue authorities are monitoring daily and monthly rainfall data at taluka headquarters and the same data up to 2022 is used for the data entry. The IMD published taluka wise normal rainfall figures are also used.

Besides these, the hydro-meteorological stations, data from Water Resources Department, GSDA has been considered during this assessment.

4.1.7 Groundwater Levels

The Groundwater Surveys and Development Agency is monitoring the groundwater levels in the State on quarterly basis i.e. in January, March, May and September/October. In the state total 3789 observation wells (3 observation wells in each watershed). The groundwater level data up to May 2023 has been considered for the Estimation.

4.1.8 Population

The 2011 census data has been used in the computations.

4.2 VARIOUS NORMS USED

4.2.1 Assessment Area

Out of the total geographical area, the hilly area (slope > 20%), hill tops and rocky waste land were identified and subtracted and the remaining area is considered as recharge worthy or assessment area.

4.2.2 Specific yield

The specific yield value as estimated from dry season balance method or field studies was taken, wherever available. In absence of field values of specific yield values through above methods recommended values as per prescribed norms of GEC-2015 methodology were taken.

4.2.3 Rainfall infiltration factor

In all the watersheds, the coefficients for RIF are as per the recommended values of GEC-2015 methodology norms.

4.2.4 Recharge due to canal seepage

The prescribed norms of GEC-2015 methodology i.e., 15 Ham per day/million sq. m wetted area for unlined canals and 20% of it is for lined canals, have been considered.

4.2.5 Recharge from Tanks and Ponds

The prescribed norms of GEC-2015 methodology i.e., Average water spread area * No. of days * **0.00144** meters per day per Ha, has been considered.

4.2.6 Recharge from water conservation structure

The recharge considered due to water conservation structures is as per norms i.e. 50% of the total storage capacity of the water conservation structure. The number fillings considered are either 1 or 2 only. This is as per the local observations.

4.2.7 Unit Draft or Extraction

The unit draft computed for different abstraction structures representing typical geological formations has been used for the estimation. The unit draft for irrigation dug well fitted with electric pump, during monsoon ranges from 0.0047 to 0.42 hams and during non-monsoon it ranges from 0.054 to 1.56 hams. For irrigation bore wells (with electric pump), the unit draft considered for monsoon ranges from 0.0049 to 0.38 hams and for non-monsoon it ranges from 0.03 to 1.37 hams. The unit draft for domestic dug well (with power pump) ranges during monsoon ranges from 0.12 to 0.70 hams and during non-monsoon it ranges from 0.066 to 1.47 hams. The unit draft for domestic bore well fitted with hand pump ranges from 0.006 to 0.59 hams. Similarly, the unit draft for domestic bore well fitted with power pump ranges from 0.013 to 1.47 hams.

4.2.9 Return flow from irrigation

The prescribed norms of GEC-2015 methodology have been adopted which includes,

SWL<10 m	Paddy	Non-Paddy
GW	45%	25%
SW	50%	30% of total water applied has been considered.

4.2.10 Stage of Ground water Extraction and Categorisation

The norms of GEC-2015 methodology have been used for the computation of the Stage of Ground water Extraction and Categorisation.

Stage of Ground Water Extraction	Category
$\leq 70\%$	Safe
$> 70\% \text{ and } \leq 90\%$	Semi-Critical
$> 90\% \text{ and } \leq 100\%$	Critical
$> 100\%$	Over Exploited

CHAPTER 5

5. COMPUTATION OF GROUNDWATER RESOURCES ESTIMATION

5.1 SALIENT FEATURES

The salient features of the dynamic groundwater resources of Maharashtra 2023 are as under:

5.1.1 Resources assessment unit

Watershed is the type of groundwater assessment unit used in the State. For the purpose of groundwater estimation and evaluation the Maharashtra State is divided into 1534 watersheds. These watersheds are sub-divided into 2563 assessment sub-units, comprising of 992 commands, 1513 non-command and 58 poor quality units. Where the assessment unit is a watershed, the ground water assessment is apportioned to an administrative unit such as Block/Taluka/Mandal. Groundwater estimation and evaluation is carried out of 353 talukas. Out of this, 307 taluka comes under only command area, 351 taluka comes under only non-command area and 29 taluka comes under poor quality area. The watershed wise details of these areas are given in **Annexure A-II**.

Out of the total area of the taluka the non-worthy area is deducted and only the worthy area is considered for this assessment. The worthy area is further sub-divided into command; Non-command & Poor quality and their percentages for the State are 14.75%, 84.17% & 1.07% respectively. The taluka wise details of these areas are given in **Annexure A-I**. The recharge is estimated for the groundwater worthy area of all the sub-units.

5.1.2 Base year of data

The monsoon rainfall for the year 2022 has been considered in the computations. The groundwater levels from 1991 up to May 2023 have been used in the calculations. Based on this database the sub-unit wise average pre-monsoon and post-monsoon groundwater levels and fluctuations are calculated and used in the assessment.

5.2 GROUNDWATER RESOURCE ASSESSMENT

5.2.1 Method

For the assessment to the all-sub-units, the water table fluctuation (WTF) method and the Rainfall Infiltration (RIF) method are adopted. Generally, most of the sub-units are assessed based on the groundwater level data.

5.2.2 Total Resources

The groundwater estimation is carried out for 34 districts of Maharashtra except for Greater Bombay & Sub-urban district due to paucity of data and highly dense urban set up. As per the protocol the groundwater availability and use has been computed for the sub-units, but the categorization has been done for the watershed. For administrative purpose the watershed wise assessment has been apportioned into 353 talukas and their categorization has been worked out separately. The State abstract showing details of Dynamic Groundwater Resources 2023 is given in **Table 3**.

TABLE 3- Information at a Glance of Ground Water Resource Assessment 2023

Sr. No	Description	Details
1	Total No. of Districts Assessed in the State	34
2	Total No. of watersheds in the State	1534
3	Total No. of Talukas in the State	353
4	Total No. of Assessment Sub Units	2563
5	Annual Groundwater Recharge (BCM)	32.76
6	Annual Extractable Ground Water Resource (BCM)	30.95
7	Total Extraction (BCM)	16.66
8	Ground Water Extraction for Irrigation Use (BCM)	15.28
9	Ground Water Extraction for Domestic and Industrial Uses (BCM)	1.39
10	Stage of Ground water extraction of Maharashtra	53.83%
11	Total No. of Irrigation Wells	24,38,844
12	Total No. of Domestic Wells	1,46,821
13	Total No. of Industrial Wells	10,149
14	No. of Over Exploited Talukas	9
15	No. of Critical Talukas	9
16	No. of Semi Critical Talukas	57
17	No. of Safe Talukas	277
18	Unclassified Assessment taluka due to entire Poor Quality	1

As per this report, the total rechargeable fresh groundwater resources in the State is computed as 32.76 BCM and the Annual Extractable Ground Water Resource is to the tune of 30.95 BCM. The Total Extraction is 16.66 BCM. The Stage of groundwater development for the State, as whole, is 53.83%. This indicates that on an average 53.83 % of yearly replenishable groundwater is being used in the State.

Considering the domestic and industrial requirement the annual ground water allocation for domestic water supply as on March 2025 is 1.42 BCM. Leaving this allocation, the net groundwater availability for future use Development is around 14.81 BCM. The taluka wise details of groundwater recharge from rainfall & other sources in monsoon and non-monsoon season, Total Annual Groundwater Recharge and Annual Extractable Groundwater Resources, are given in **Annexure- B**.

The recharge from rainfall during monsoon and non-monsoon has been computed separately sub-unit wise. However, for few talukas of Ahmednagar, Akola, Amravati, Aurangabad, Bhandara, Dhule, Gadchiroli, Hingoli, Jalgaon, Nagpur, Nashik, Parbhani, Solapur and Wardha districts the rainfall recharge during non-monsoon season is zero. This is because in these districts the areas are receiving rainfall less than 10 % of normal monsoon rainfall and hence rainfall recharge is ignored as per the GEC 97 norms.

In the absence of non-availability of the base flow data, the Natural Discharge is computed as per the GEC97 norms for the sub-units. Within a district there is a variation in the natural discharge (either 5 % or 10 %). It is because in most of the watersheds the recharge has been computed by the WTF method but where there is difference in PD factor the computations are done by RIF.

5.2.3 Groundwater Abstraction

The basic pre-requisite for the groundwater assessment is the number of groundwater abstraction structures and their draft. For this assessment IVth well census data have been used for most of the watersheds. However, where the data was insufficient or less the Revenue Department data pertaining to wells have been considered. As per this database, it is found that in all there are 24.39 lakh abstraction structures being used for irrigation purpose withdrawing 15.39 BCM of groundwater **yearly** (Fig 1).

Fig. 1. Long term variation in irrigation wells and GW Extraction

As per the database received for domestic wells (dug wells & bore wells), there are 0.52 lakhs domestic dug wells and 0.94 lakhs bore wells which accounts for 0.013 BCM and 0.0099 BCM of ground water draft, respectively. The total domestic draft is 0.022 BCM.

Fig. 2: District wise Irrigation wells senses

During this assessment, data of 24.39 lakh irrigation bore wells have been reported in the well census withdrawing 0.004 BCM of groundwater. However, this number could be much higher. Now the irrigation dug wells are being replaced by irrigation bore wells. This practice is very prominent in Latur, Osmanabad, Ahmednagar, Amravati, Nashik, Pune, Solapur, Sangli & Satara districts. However, even after knowing the disadvantages of irrigation bore wells, like low dependability of yield, low discharge & low recuperation rate etc, still the farmers are opting for irrigation bore wells. The district wise irrigation bore wells are shown in **figure 2**

For domestic purpose most of the rural area is dependent on groundwater. There are 1.46 lakh bore wells & Dug wells using only 0.023 BCM of groundwater for domestic purpose.

In the State, the industries are also using groundwater. Total of 10149 number of DW/BW using negligible quantity of groundwater. However actual wells must be much higher but due to paucity of data the actual ground water withdrawal for industrial purpose is not getting reflected.

5.2.4 Groundwater Recharge

As compared to 2022 assessment, the Annual Ground Water Recharge in 2023 has increased from 32.28 to 32.76 BCM, Annual Extractable Ground Water Recharge from 30.45 to 30.95 BCM and Annual Ground Water Extraction from 16.65 to 16.66 BCM. There is a marginal decrease in the Stage of Ground Water Extraction from 54.68 % to 53.83 %. The marginal increase in recharge due to the State government intervention of water conservation activities and the marginal increase in draft/extraction is due to revision of well census data on the basis of functional wells.

5.2.5 Future Allocations for Domestic & Industrial Allocations

As per the recommendations of the State Level Committee it has been decided to categorize the watershed/taluka. Hence all the computations, including the Future Domestic & Industrial Allocations, are done on watershed basis only. The apportioning has been done on taluka and district level. The Future Domestic & Industrial Allocations is either $\geq$ the existing Domestic & Industrial draft or zero, where there is no groundwater balance after deducting the actual drafts for different usages. This situation is prevailing in most of the over-exploited, critical and some semi-critical watersheds. Accordingly, the same has been mentioned in the **Annexure C**.

5.2.6 Categorization of Talukas

The categorization of talukas is done as per the norms mentioned in GEC-2015 methodology. Based on these computations, it is observed that **277** talukas are falling in Safe category, **57** in Semi-Critical, **9** in Critical, **9** in Over-Exploited category and **1** taluka is categorized as unclassified due to Poor Quality. Taluka wise categorization are given in **Annexure D**. The categorization of talukas is also shown on the State Taluka **Map 5**. From this map, it reveals that two-third of the over-exploited, Critical and Semi-Critical talukas are from drought prone area of the State, where the rainfall is between 400 to 700 mm only. The district wise abstract showing number of OE/Critical/SC/Safe & PQ talukas is given in **Annexure E**.

5.3 SPATIAL VARIATION

5.3.1. Groundwater Development

The central part of Maharashtra which is included in the drought prone area, receives very less rainfall i.e., from 400 to 700 mm, but the geology is favourable for the groundwater recharge. Hence, in this area the dependency on groundwater is very high. Two-third of irrigation wells are from this area only. This primarily includes parts from Nashik, Jalgaon, Ahmednagar, Buldhana, Amravati, Pune, Satara, Sangli, Solapur, Osmanabad, Beed and Aurangabad districts.

Fig. 3. District Wise Recharge and Extraction

The comparison of district wise groundwater recharge and withdrawal clearly shows that in Amravati, Ahmednagar, Aurangabad, Jalgaon, Buldhana, and Solapur district the groundwater development is between 70 to 90 %. However, in Satara, Pune, Akola, Osmanabad, Washim, Beed, Nashik, Wardha, Latur, Jalna, Sangli and Dhule districts, the development is between 50 to 70% and in rest 15 districts it is <50% % (**fig 3**). In Nashik, Ahmednagar, Pune, Amravati, Jalgaon districts the irrigation well density is also very high i.e., from 10 to 15 wells/sq km.

Fig 4. Percentage of total Abstracted Talukas

The groundwater development i.e., number of Over-exploited, critical and semi-critical Talukas are highest in Jalgaon (12), Ahmednagar (10), Buldhana (9), Pune (8), Solapur (8), Amravati (8), Aurangabad (7), Nashik (6), followed by Nagpur (1), Osmanabad (2), Satara (2), Akola (1), Latur (1), and Sangli (1) (**fig 4**). The over withdrawal of groundwater in these districts is attributed to the water intensive cash crop like Sugarcane, Banana, Grapes and Oranges, which are mostly groundwater dependent.

5.3.3 Groundwater Levels

The ground water level is the pulse of aquifer and the groundwater abstraction or the natural discharge has a direct impact on the groundwater levels. During this assessment, the post-monsoon groundwater levels of 2022 and pre-monsoon groundwater levels of 2023 are considered for computations.

5.4 COMPARISON WITH THE EARLIER ASSESSMENTS

5.4.1 Assessment Units

Since 1973, watershed is being used as a unit for assessment in the State irrespective of the methodology. Comparison between the Groundwater resource assessments in the State based on GEC 84 (1988), GEC-97 and GEC-2015 guidelines (2004, 2007-08, 2008-09, 2011-12 & 2013-14, 2017, 2020 & 2022) has been carried out. The comparison clearly shows that with the increasing ground water development; there is increase in number of over-abstracted watersheds. However, in the current year due to consistency in the rainfall for the last five years and because of increase in recharge from other sources (except Tanks and Ground Water irrigation structures), there is marginal decrease in the number of over-developed (OE/C/SC) watersheds. **Annexure F** shows the no. of assessment units improved and deteriorated compared to GWRE 2022.

Since 1988 the numbers of over abstracted watersheds have alarmingly increased till 2004. Subsequently, from 2007 onwards the number has started decreasing due to consistent good rainfall years supported by massive measures of artificial groundwater recharge.

The importance of groundwater resource for irrigation purposes is critical hence the development has been receiving the attention from the farmers. In the year 1988 there were 10.07 lakh irrigation wells and now in the year 2023 i.e., as per IVth Well Census, the number has gone up to 24.39 lakhs.

5.4.2 Recharge

The past good rainfall years supported by the development of new surface irrigation systems, recycled the surface water and replenished the groundwater in the non-monsoon period. The operationalization and distribution of surface water through newly constructed major, medium minor and lift irrigation projects/schemes have indirectly contributed to increase in the groundwater, either through irrigation return flow or by non-pumping of groundwater.

TABLE 4- Recharge from different sources in BCM

Year	Rainfall	Canal	SW Irri.	GW Irri	Tank &Ponds	WCS	Total Recharge
2004	22.08	0.52	4.11	3.54	0.33	2.38	32.96
2008	23.94	0.53	4.2	4.03	0.31	2.73	35.73
2011	24.2	0.51	3.74	4.13	0.3	1.06	33.95
2013	23.78	0.47	3.4	4.07	0.3	1.17	33.19
2017	21.11	0.44	4.5	3.89	0.34	1.33	31.63
2020	21.39	0.46	4.73	3.97	0.35	1.53	32.42
2022	21.26	0.50	4.8	3.93	0.35	1.54	32.61
2023	21.61	0.49	4.86	3.95	0.36	1.74	33.01

The initiative taken by GoM and community in last decade, in artificial groundwater recharge, has shown the remarkable results due to the increased number of WCS structures under the various water conservation schemes taken by State Govt. under its various schemes like Jalyukt Shivar, IWMP etc.

5.5 GROUNDWATER RECHARGE IN POOR QUALITY ZONE

The poor-quality area in the State has increased from 305308 ha (2004) to 361858 ha (2023). This mainly includes the area from Saline Belt of Purna River. This is in-situ saline tract where TDS is very high.

Besides this in Western part of Maharashtra i.e., Sangli, Pune, Ahmednagar Districts due to excessive surface irrigation and use of chemical fertilizers the area is becoming saline. This increase is mainly in Sangli and Ahmednagar districts. During this assessment the watershed wise recharge from rainfall and other sources along with the gross groundwater draft has been computed separately for the poor-quality area. The total recharge is of the order of 28278.34 ham and the draft is about 22926.39 ham.

5.6 ANNUAL POTENTIAL RECHARGES

In Maharashtra, the water logged and shallow water table areas are very sporadic. Their aerial extent is very small and it is very difficult to map and monitor. Hence, computation of potential recharge to ground water reservoir i.e., potential ground water resource has not been computed.

5.7 THE SUMMERY OF GWRE-2023

Strategy Adopted for GWRE-2023:

Data Entry made by district officials of GSDA, after data entry First Level Scrutiny will be done by district Senior Geologists, Second Scrutiny done by Regional Deputy director, GSDA and final Reconciliation and Scrutiny with CGWB, Nagpur (GoI) and Directorate GSDA. The Database used for GWRE-2023 are as following:

TABLE 5: DATABASE USED FOR GWRE-2023

Parameters	Base year (As on 2022)	Source Department
▪ Rainfall	2022-23	Revenue
▪ GW level	Up to May 2023	GSDA
▪ Domestic Wells-Rural	Up to 2023	RWS, ZP
▪ Domestic Wells-Urban	Up to 2023	ULBs
▪ Irrigation Wells	Up to 2023	Revenue
▪ Cropping Details	2022-23	Agriculture
▪ Canal Rotations	2022-23	Jalsampada (WRD)
▪ Tanks and Ponds	Up to 2023	WRD / WCD / MI ZP
▪ WCS	Up to 2023	Agriculture/WCD/MI ZP/GSDA

GWRE-2023 AT A GLANCE:

Total Annual Ground water recharge of the Maharashtra is 32.76 BCM excluding Total Natural Discharge 1.82 BCM (Fig.5). Annual Extractable Ground Water Resource is 30.95 BCM, whereas current annual ground water extraction is 16.66 BCM and net ground water availability for future is 14.81 BCM.

Fig 5: GWRE-2023 Recharge and Extractable groundwater quantum

Ground Water Recharge at a Glance – 2023

The total ground water recharge distribution by various components is presented in Fig.6 is clearly showing rainfall (65.26%) is the major contributor followed by Surface water and ground water irrigation (14.86 and 11.91%). The total no. of wells under Industrial, domestic and Irrigation for calculating Ground Water Extraction component is presented in Table no.6.

Fig 6: Distribution of Ground water recharge

TABLE 6: GROUNDWATER DRAFT COMPONENTS

GW Draft components	2021-2022			2022-2023		
	No. of wells	Draft in BCM	Draft %	No. of Wells	Draft in BCM	Draft %
Domestic	382659	1.313	8.12	386940	1.355	8.11
Irrigation	2420305	14.852	91.86	2438844	15.312	91.72
Industrial	8000	0.003	0.02	10149	0.027	0.16
Total	2810964	16.168	100	2835933	16.694	100

GWRE-2023 recharge component wise comparison with previous year GWRE-2022 is presented in Table-7. Significant increase in the recharge components of the Water Conservation Structures (0.62%) and Surface water irrigation component (0.36%) is observed in compared to GWRE-2022.

Components	2021-22		2022-23		Difference	
	In BCM	%	In BCM	%	In BCM	%
Rainfall	20.55	65.951	21.38	65.25	0.83	-0.7
Canal	0.49	1.558	0.49	1.52	0	-0.03
SW Irrigation	4.52	14.501	4.86	14.86	0.34	0.36

GW Irrigation	3.79	12.169	3.9	11.91	0.11	-0.25
Tanks	0.35	1.109	0.36	1.11	0.01	0.01
WCS	1.47	4.713	1.74	5.33	0.27	0.62
Total	31.15	100	32.76	100	1.61	0.00

TABLE NO. 7: COMPONENT WISE VARIATIONS IN RECHARGE

GWRE-2023 block wise categorization observed that the no. of safe category taluka is increased from 272 to 277, the Semi-Critical reduced to 57 from 62, as well Critical increased and Over-exploited reduced in 2 talukas respectively, no change in number of saline taluka. The details are as given in table no. 8.

TABLE 8: CATEGORIZATION OF TALUKAS AND COMPARISON WITH PREVIOUS ESTIMATIONS

Category of Talukas	No. of Talukas in 2017	No. of Talukas in 2020	No. of Talukas in 2022	No. of Talukas in 2023	Difference in Taluka category as compared to 2022
Safe	271	271	272	277	+5
Semi-critical	61	63	62	57	-5
Critical	9	8	7	9	+2
Over Exploited	11	10	11	9	-2
Poor Quality	1	1	1	1	0
Total	353	353	353	353	

MINUTES OF STATE LEVEL TECHNICAL COMMITTEE (SLTC) MEETING ON 04th September 2023.

The State Level Committee (SLC) on GWRE-2023 meeting was held on 04.09.2023 at 15.15 PM in the Conference Hall, Water Supply & Sanitation Department, 7th Floor, Mantralaya, Mumbai under the Chairmanship of Hon. Sanjay Khandare, IAS, Principal Secretary, WS & S Department, Government of Maharashtra for approval of Ground Water Resource Estimation 2023 for the State of Maharashtra.

At the outset, Shri N. Varadaraj, Regional Director, Central Ground Water Board and Member Secretary of the Ground Water Resource Estimation (GWRE)2023, welcomed Hon. Sanjay Khandare, IAS, Principal Secretary, WS & S Department, Government of Maharashtra and Chairman of the Committee, other Members and representatives from various Departments/Universities. Regional Director, Central Region, CGWB briefed on the agenda of the meeting i.e., approval of GWRE-23 for the State of Maharashtra assessed through IN-GRES (INDIA-Groundwater Resource Estimation System) software jointly by GSDA & CGWB and requested the Chair to preside over the proceedings.

The Chair, Dr. Vijay Pakhmode, Joint Director, GSDA, Maharashtra made PPT presentation on the salient features of Maharashtra, including rainfall pattern, geographical & hydrogeological settings, aquifer disposition in basalt rock, and background of GWRE and also informed that GEC-2015 Methodology was adopted in making computations through IN-GRES software and the data was compiled watershed wise and analyzed for the entire state and further added that rainfall, recharge from tanks, water conservation structures viz., check dams, percolation tanks, extraction of resource for agricultural, domestic, industrial and drinking water requirements were the components taken into consideration while computing the resource. Dr. Pakhmode further made detailed presentation on ground water resource availability as per GWRE-23 in comparison with GWRE-22 resources, and informed that total annual extractable groundwater resource available is 30.95 BCM, current annual ground water extraction is 16.66 BCM and further ground water availability for future use is 14.81 BCM. Dr. Pakhmode further informed that 65.26% ground water recharge is from rainfall followed by SW irrigation (14.86%), ground water irrigation contributes about 11.91%, water conservation structures contribute 5.33% and rest by return flow from canal (1.53%) and tanks (1.11%) and also informed that out of 353 blocks, 79% blocks (277 nos.) fall in safe category and stressed on reduction in Over Exploited and Semi-Critical blocks from 11 to 9 nos and from 62 to 57 nos respectively, and increase of critical blocks from 7 to 9 nos and no changes in poor quality blocks as compared to 2022 estimates. Overall, there is an improvement in the annual extractable ground water resources and reduction in ground water extraction compared to previous GWRE.

The Chairman of the Committee, Hon. Sanjay Khandare, IAS, the Principal Secretary pointed out that the impact of good rainfall in the last 3 years and water conservation measures taken by Govt. in water sector on groundwater resource availability for which Dr. Pakhmode, JD, GSDA replied in detail and also explained how these resources data is considered while implementing schemes like Atal Bhujal Yojana, Artificial Recharge Schemes, Catch the Rain campaign etc.

During the discussions, the Chairman of the committee and Principal Secretary appreciated the efforts of CGWB & GSDA in completing the assessment and finally approved the Dynamic Ground Water Resources - 2023 (GWRE-2023) for the state of Maharashtra. The meeting ended with the vote of thanks by Dr. Pramod Reddy, Dy. Director, GSDA.

ENCLOSURES

Enclosure-I:

State Govt. vide letter no. Bhujal-1822/C.R.29/WS-15 dated 27th Jan 2022, constituted The State Level Committee for Estimation of Ground Water Resources based on GEC-2015 Methodology

State Level committee for
Estimation of Ground
water Resources as on
March 2022 based on GEC
2015 methodology.

Government of Maharashtra
Water Supply and Sanitation Department
Government Resolution No.: Bhujal-1822/C.R.29/WS-15

2. Letter from Regional Director, CGWB, Central region Nagpur, Ministry of Water Resources, River Development and Ganga Rejuvenation No.: 20/2/TS-16 dated- 05/01/2022

Introduction:-

In accordance with the directives received from the ministry of Jalshakti, Water Resources, River Development and Ganga Rejuvenation, Central Groundwater Board, Government of India, Nagpur vide letter dated- 05/01/2022, Re-assessment of Ground Water Resources for the year 2021-2022 has to be carried out based on a methodology recommended by "Ground Water Estimation Committee-2015 Methodology" (GEC-2015) jointly by CGWB and State Ground Water Department for the State of Maharashtra based on the current ground water data in view of the changes observed in the ground water scenario. The last assessment of annual replenishable ground water resources for the state of Maharashtra was carried out for the water year 2019-20 based on GEC-2015 Methodology. The National Water Policy, 2012 has also recommended that the ground water resources of the country should be re-assessed periodically.

Page 1 of 5

In order to estimate Ground Water Resources of the State for year 2021-22 in accordance with GEC-2015 Methodology, a State Level Committee is required to be constituted as directed by Government of India.

Resolution:-

With the view to re-assess ground water resources for the water year 2021-22, the Government of Maharashtra has decided to constitute the State Level Committee (SLC) for re-assessment the Ground Water Resources for the year 2021-22 based on GEC-2015 Methodology for the State of Maharashtra with following composition:

Sr. No.	Designation	Designation in the Committee
1	Additional Chief Secretary/Principal Secretary, Water Supply And Sanitation Department, Government of Maharashtra Mantralaya, Mumbai-440001	Chairman
2	Principal Secretary, Rural Development and Water Conservation Government of Maharashtra Mantralaya, Mumbai-440 032	Member
3	Principal Secretary, Urban Development Department, Government of Maharashtra Mantralaya, Mumbai-440 032	Member
4	Commissioner Agriculture, Pune	Member
5	Commissioner Department of Industries, Opp. Mantralaya Mumbai	Member
6	Chief Engineer & Jt. Secretary Water Resources Department, Government of Maharashtra, Mumbai	Member
7	Commissioner, Groundwater Surveys and Development Agency, Pune	Member
8	Director, Maharashtra Remote Sensing Application Centre (MRSAC) Nagpur	Member
9	Director, Directorate of Municipal Administration (DMA) Worli, Mumbai	Member
10	Director, Soil Conservation & Watershed Development, Pune	Member
11	Chief Engineer, Minor Irrigation-Local Sector, Pune	Member

Sr. No.	Designation	Designation in the Committee
12	Chief Engineer, Maharashtra State Electricity Distribution Company Limited (MSEDCL) Mumbai	Member
13	General Manager NABARD, Pune	Member
14	Secretary, Maharashtra Water Resources and Regulatory Authority, (MWERRA), World Trade Centre, Mumbai	Member
15	Representative of Mahatma Phule Agricultural University, Rahuri	Member
16	Regional Director, Central Ground Water Board, Government of India, Nagpur	Member Secretary

The committee may co-opt any other member (s) special invitee (s), if necessary

(2) Terms of Reference:-

The broad terms of reference of the Committee would be as follows:

- 1) To re-assess annual replenishable ground water resources of the State of Maharashtra for the year 2021-22 in accordance with GEC-2015 Methodology.
- 2) To estimate the status of utilization of the annual replenishable ground water resource.
- 3) To submit the ground water resource estimates of the State to Central Level Expert Group (CLEG) after the approval of SLC for inclusion in National level report on assessment of ground water resources.
- 4) Any other aspect relevant to the terms referred to above.

3) Time Frame

The Committee will submit its report on or before 28-02-2023 to Government of India after the approval of SLC.

4) Expenditure

Expenditure on account of TA/DA to official Members of the SLC will be met from the source from which they draw their salaries.

This Government resolution of Maharashtra Government is available at the website www.maharashtra.gov.in. Reference no. for this is 202201271036087728. This Order has been signed digitally.

By Order and in the name of the Governor of Maharashtra.

2. Letter from Director, G.S.D.A. Pune No.: मुसुडिय/सडिक/भुजल मुल्यांकन २०२१-२०/२५४/२०२२, दि. ३० मार्च, २०२२

Introduction:-

In accordance with the directives received from Ministry of Jal Shakti, Department of Water Resources, River Development and Ganga Rejuvenation, Central Groundwater Board, Govt. of India, Nagpur vide letter no.No.20/2/TS-16, dated 05 January, 2022 and mail dated 24.03.2022, there-assessment the Ground Water Resources for the year 2021-22 and for subsequent regular and periodic assessment as per the directives issued by Ministry of Jal Shakti, Govt. of India from time to time has to be carried out based on a methodology recommended by "Ground Water Estimation Committee 2015Methodology" (GEC-2015) jointly by CGWB and State Ground Water Department for the State of Maharashtra based on the current ground water data in view of the changes observed in the ground water scenario. The last assessment of annual replenishable ground water resources for the state of Maharashtra was carried out for the water year 2019-20based on GEC-2015Methodology. The National Water Policy, 2012 has also recommended that the ground water resources of the country should be re-assessed periodically.

In order to estimate Ground Water Resources of the State in accordance with GEC-2015 Methodology, a Permanent State Level Committee is required to be constituted as directed by Government of India.

1) Resolution:

With the view to re-assess ground water resources for the State of Maharashtra, the Government of Maharashtra has decided to constitute the Permanent State Level Committee (SLC) for re-assessment the Ground Water Resources for the year 2021-22 and for subsequent regular and periodic assessment as per the directives issued by Ministry of Jal Shakti, Govt. of

India from time to time based on *GEC-2015 Methodology for the State of Maharashtra* with following composition:

1)	Additional Chief Secretary/Principal Secretary, Water Supply and Sanitation Department, Govt. of Maharashtra, G.T. Hospital Complex, Mumbai-440001.	Chairman
2)	Principal Secretary, Rural Development Department, Govt. of Maharashtra, Mantralaya, Mumbai-440 032	Member
3)	Principal Secretary, Urban Development Department, Govt. of Maharashtra, Mantralaya, Mumbai-440 032	Member
4)	Commissioner, Agriculture, Pune	Member
5)	Commissioner, Department of Industries, Opp. Mantralaya, Mumbai	Member
6)	Chief Engineer & Joint Secretary, Water Resources Department, Govt. of Maharashtra, Mantralaya, Mumbai	Member
7)	Commissioner, Groundwater Survey and Development Agency, Pune	Member
8)	Director, Maharashtra Remote Sensing Application Centre (MRSAC), Nagpur	Member
9)	Director, Directorate of Municipal Administration (DMA), Work, Mumbai	Member
10)	Director, Soil Conservation & Watershed Development, Pune	Member
11)	Chief Engineer, Minor Irrigation - Local Sector, Pune	Member
12)	Chief Engineer, Maharashtra State Electricity Distribution Company Limited (MSEDCL), Mumbai	Member
13)	General Manager, NABARD, Pune	Member
14)	Secretary, Maharashtra Water Resources and Regulatory Authority, (MWRRA), World Trade Centre, Mumbai	Member
15)	Representative of Maharashtra Pledge Agricultural University, Rahuri	Member
16)	Regional Director, Central Ground Water Board, Government of India, Ministry of Jal Shakti, Department of Water Resources, River Development and Ganga Rejuvenation, Central Region, Nagpur.	Member Secretary

The Committee may co-opt any other Member (s) /special invitee (s), if necessary.

2) **Terms of Reference:** The broad terms of reference of the Committee would be as follows:

- 1) To re-assess annual replenishable ground water resources of the State of Maharashtra for the year 2021-22 and for subsequent regular and periodic assessment as per the directives issued by Ministry of Jal Shakti, Govt. of India from time to time in accordance with GEC-2015 Methodology.
- 2) To estimate the status of utilization of the annual replenishable ground water resource.

- 3) To submit the ground water resource estimates of the State to Central Level Expert Group (CLEG) after the approval of SLSC for inclusion in National level report on assessment of ground water resources.

- 4) Any other aspect relevant to the terms referred to above.

3) Time Frame

The Committee will submit its report on or before 30.09.2022to Government of India after the approval of SLC.

5) Expenditure

Expenditure on account of TA/DA to official Members of the SLC will be met from the source from which they draw their salaries.

This Government resolution of Maharashtra Government is available at the website www.maharashtra.gov.in. Reference no. for this is 202207151255483428. This Order has been signed digitally.

By Order and in the name of the Governor of Maharashtra.

**RAJENDRA
MAHADEV GENGAJE**

Digitally signed by Rajendra Mahadev Gengaje, DN: cn=Rajendra Mahadev Gengaje, o=Government of Maharashtra, ou=Ministry of Water Resources, email=rajendra.gengaje@gov.in, c=IN
